ROYAL COMMISSION ON WATER SUPPLY.

REPORT

REFORM CLUB
PALL MALL

OF

THE COMMISSIONERS.

Presented to both Houses of Parliament by Command of Her Majesty.

LONDON:
PRINTED BY GEORGE EDWARD EYRE AND WILLIAM SPOTTISWOODE,
PRINTERS TO THE QUEEN'S MOST EXCELLENT MAJESTY.
FOR HER MAJESTY'S STATIONERY OFFICE.

1869.

ORIGINAL COMMISSION.

VICTORIA R.

Victoria, by the grace of God of the United Kingdom of Great Britain and Ireland Queen, Defender of the Faith.

To Our right trusty and right entirely-beloved Cousin and Councillor Charles Henry Duke of Richmond; Our trusty and well-beloved Sir John Thwaites, Knight; Henry Drury Harness, Esquire, Companion of Our most Honourable Order of the Bath, Colonel in Our Corps of Royal Engineers; Benjamin Samuel Phillips, Esquire, one of the Aldermen of Our City of London; Thomas Elliot Harrison, Esquire; and Joseph Prestwich, Esquire; greeting.

Whereas We, taking into Our Royal consideration that an ample supply of wholesome water at all times is of essential importance to the health of the population, especially in large towns:

And whereas the present supply delivered in the Metropolis, as well as in many other large towns, has been found insufficient, and is likely to become more so as the population increases, unless some additional sources of supply can be permanently provided:

And whereas a large portion of the water now supplied to the Metropolis and other large towns is drawn from rivers and open streams which pass through populous districts, and are therefore continually exposed to pollution from various causes:

Now know ye, that We have deemed it expedient that a Commission should forthwith issue for the purpose of ascertaining what supply of unpolluted and wholesome water can be obtained by collecting and storing water in the high grounds of England and Wales, either by the aid of natural lakes or by artificial reservoirs at a sufficient elevation for the supply of the large towns, and to report, firstly, which of such sources are best suited for the supply of the Metropolis and its suburbs; and, secondly, how the supply from the remaining sources may be most beneficially distributed among the principal towns.

And further know ye, that We, reposing great confidence in your zeal and ability, have authorized and appointed, and do by these Presents authorize and appoint, you the said Charles Henry Duke of Richmond, Sir John Thwaites, Henry Drury Harness, Benjamin Samuel Phillips, Thomas Elliot Harrison, and Joseph Prestwich, to be Our Commissioners for the purposes aforesaid.

And for the better enabling you to form a sound judgment on the premises We do hereby authorize and empower you, or any three or more of you, to call before you, or any three or more of you, all such persons as you may judge most competent by reason of their situation, knowledge, and experience, to afford you correct information on the subject of this Inquiry.

And it is Our further will and pleasure that you, or any three or more of you, do, with as little delay as possible, report to Us in writing under your hands and seals your several proceedings by virtue of this Our Commission, together with your opinion on the several matters herein submitted for your consideration.

And We will and command that this Our Commission shall continue in full force and virtue, and that you, Our Commissioners, or any three or more of you, may from time to time proceed in the execution thereof, although the same be not continued from time to time by adjournment.

And for your assistance in the execution of this Our Commission, We do hereby authorize and empower you to appoint a Secretary to the said Commission, whose services and assistance We require you to use from time to time as occasion may require.

Given at Our Court at St. James's, the twenty-fourth day of December 1866, in the thirtieth year of Our Reign.

By Her Majesty's command.

S. H. WALPOLE.

NEW COMMISSION.

VICTORIA R.

Victoria, by the grace of God of the United Kingdom of Great Britain and Ireland Queen, Defender of the Faith.

To Our right trusty and right entirely-beloved Cousin and Councillor Charles Henry Duke of Richmond, Knight of Our Most Noble Order of the Garter; Our trusty and well-beloved Sir John Thwaites, Knight; Henry Drury Harness, Esquire, Companion of Our most Honourable Order of the Bath, Colonel in Our Corps of Royal Engineers; Sir Benjamin Samuel Phillips, Knight, one of the Aldermen of Our City of London; Thomas Elliot Harrison, Esquire; and Joseph Prestwich, Esquire; greeting.

Whereas We, taking into Our Royal consideration that an ample supply of wholesome water at all times is of essential importance to the health of the population, especially in large towns:

And whereas the present supply delivered in the Metropolis, as well as in many other large towns, has been found insufficient, and is likely to become more so as the population increases, unless some additional sources of supply can be permanently provided:

And whereas a large portion of the water now supplied to the Metropolis and other large towns is drawn from rivers and open streams which pass through populous districts, and are therefore continually exposed to pollution from various causes:

And whereas We did, by Warrant under Our Royal Sign Manual bearing date the Twenty-fourth day of December last, appoint you to be Our Commissioners for the purpose of ascertaining what supply of unpolluted and wholesome water can be obtained by collecting and storing water in the high grounds of England and Wales, either by the aid of natural lakes or by artificial reservoirs at a sufficient elevation for the supply of the large towns, and to report, firstly, which of such sources are best suited for the supply of the Metropolis and its suburbs; and, secondly, how the supply from the remaining sources may be most beneficially distributed among the principal towns.

Now know ye, that We have revoked and determined, and do by these Presents revoke and determine, the said Warrant bearing date the Twenty-fourth day of December last, and every matter and thing therein contained.

And further know ye, that We, reposing great confidence in your zeal and ability, have authorized and appointed, and do by these Presents authorize and appoint, you the said Charles Henry Duke of Richmond, Sir John Thwaites, Henry Drury Harness, Sir Benjamin Samuel Phillips, Thomas Elliot Harrison, and Joseph Prestwich, to be Our Commissioners for the purpose of ascertaining what supply of unpolluted and wholesome water can be obtained by collecting and storing water in the high grounds of England and Wales, either by the aid of natural lakes or by artificial reservoirs at a sufficient elevation for the supply of the large towns, and to inquire into the present Water Supply to the Metropolis, and whether there are other districts in addition to the high districts of England and Wales from which a good supply of unpolluted and wholesome water can

be obtained; and to report, firstly, which of such sources are best suited for the supply of the Metropolis and its suburbs; and, secondly, how the supply from the remaining sources may be most beneficially distributed among the principal towns.

And for the better enabling you to form a sound judgment on the premises We do hereby authorize and empower you, or any three or more of you, to call before you, or any three or more of you, all such persons as you may judge most competent by reason of their situation, knowledge, or experience, to afford you correct information on the subject of this Inquiry.

And Our further will and pleasure is that you, or any three or more of you, do, with as little delay as possible, report to Us in writing under your hands and seals your several proceedings by virtue of this Our Commission, together with your opinion on the several matters herein submitted for your consideration.

And We will and command that this Our Commission shall continue in full force and virtue, and that you, Our said Commissioners, or any three or more of you, may from time to time proceed in the execution thereof, although the same be not continued from time to time by adjournment.

And for your assistance in the execution of this Our Commission, We do hereby authorize and empower you to appoint a Secretary to the said Commission, whose services and assistance We require you to use from time to time as occasion may require.

Given at Our Court at St. James's the Fourth day of April 1867, in the thirtieth year of Our Reign.

By Her Majesty's command.

(Signed) S. H. WALPOLE.

CONTENTS OF THE REPORT.

PAR.

1. Objects of the inquiry.
2. Division of the Report.

PART I.

ON THE PRACTICABILITY OF OBTAINING LARGE SUPPLIES OF WATER FROM THE MOUNTAINOUS DISTRICTS OF ENGLAND AND WALES.

3. Plans for this purpose.

MR. BATEMAN'S PLAN.

4. Date and first publication.

GENERAL DESCRIPTION OF THE SCHEME.

5. Reasons for choice of source.
6. Nature of gathering ground.
7. Conduits to bring the water to London.
8. Reservoirs near London.
9. Distribution of the water in the metropolis.
10. Supply to provincial towns on the way.

EVIDENCE AS TO THE SCHEME.

11. Quantity of water obtainable.
12. Area of gathering ground.
13. Rainfall: Mr. Bateman's estimate of quantity.
14. Objections.
15. Storage reservoirs.
16. Objections.
17. Quality of the water.
18. Influence on this of the nature of the ground.
19. Analyses of water.
20. Objections to the quality:
    (1.) Cultivated land.
21. (2.) Manufactories.
22. (3.) Mineral workings.
23. (4.) Peat.
24. (5.) Action on lead.
25. Estimates of outlay.
26. Justification for the same.
27. Objections to the sufficiency of the estimate.
28. Financial scheme; compulsory rating.
29. Analogy to the Glasgow works.

REMARKS BY THE COMMISSION ON MR. BATEMAN'S PLAN.

30. Introductory.
31. Practicability of the scheme.
32. Uncertainty of estimates of outlay.
33. And of the calculation of income and expenditure.
34. Doubtful economy of the scheme.
35. Pumping would still be required to a considerable extent.
36. On the quality of the water.
37. On the quantity of water obtainable.
38. Probable opposition.
39. Danger of so large a population being solely dependent on one supply.
40. Danger of the collection of such large bodies of water at the head of the Severn valley.

THE CUMBERLAND LAKE SCHEME.

41. Messrs. Hemans and Hassard's plan.
42. Reasons in its favour.
43. General description.
44. Area of the districts.
45. Rainfall, and quantity of water.
46. Storage.
47. Conduit to London.

PAR.

48. Supply to other towns on the way.
49. Proposed additional supply from Bala Lake.
50. Estimate.
51. Financial scheme.
52. Quality of the water.
53. Remarks by the Commission on this scheme.

MR. HAMILTON FULTON'S PLAN.

54. Description.
55. Remarks by the Commission.

MR. REMINGTON'S PLAN.

56. Description and remarks.

MR. DALE'S PLAN.

57. Description and remarks.

REMARKS ON GRAVITATION SCHEMES GENERALLY.

58. Insufficient experience with plans of this kind.
59. Their testing by the long drought of 1868.
60. Their failure in many towns.
61. Causes of this.
62. Irregularity of rainfall.
63. Difficulties with storage.
64. No failure during this drought with the Thames or the Lee.

PART II.

ON SOURCES OF SUPPLY OTHER THAN THE MOUNTAINOUS DISTRICTS OF ENGLAND AND WALES.

65. List of plans involving sources of this kind.
66. *From the Thames or its tributaries.*
67. Mr. McClean's plan.
68. Mr. Bailey Denton's plan.
69. Mr. Brown's proposals.
70. Mr. Bravender's proposals.
71. *From the Lee.*
72. Mr. Mylne's plan.
73. *From the Chalk.* Remarks on this source.
74. Mr. Clutterbuck's suggestions.
75. Mr. Homersham's suggestions.
76. Mr. Barlow's suggestions.
77. Mr. Meeson's suggestions.
78. *Miscellaneous.* Mr. Hennell's scheme.
79. Mr. Ewens' scheme.
80. Mr. Telford McNeil's scheme.
81. Remarks on these various plans.

GENERAL REMARKS ON THE SOURCES AND SPRINGS IN THE THAMES BASIN.

82. Resources of the Thames basin.
83. Illustrative maps.
84. Area, rainfall, average flow, and general features of the Thames basin.
85. Geological sections.
86. General conditions of the subterranean storage.
87. The Tertiary strata.
88. The Chalk.
89. The Greensands.
90. The Wealden strata.
91. The strata overlying the Oolites.
92. The Great and Inferior Oolites.
93. Proportion of the rainfall absorbed by permeable strata.
94. Importance of this condition for the metropolitan supply.

PART III.

ON THE PRESENT WATER SUPPLY OF THE METROPOLIS.

PAR.

95. Early artificial conduits.
96. Morrys's London Bridge waterworks.
97. The New River.
98. Early water companies.
99. Waterworks in the south of London.

128. Report of the Committee.
129. River Lee Conservancy Act of 1868.

PART IV.

ON THE SUPPLY OF WATER AVAILABLE FROM THE BASIN OF THE THAMES.

130. Question of the eligibility of the Thames basin as a source of supply for the metropolis.

SECTION I.

AS TO QUANTITY.

131. Reference to the natural features of the basin.
132. Portion of the basin to be considered. Length and course of the river.
133. Rainfall, and quantity flowing off.
134. Volume of the stream at Hampton.
135. Mr. Bateman's views.
136. Views of other witnesses.
137. Minimum volume at present.
138. Quantity of water which the companies are empowered to take.
139. The present minimum quantity may be increased by storage reservoirs.
140. Evidence on this point.
141. Inferences from this evidence.

SUBSIDIARY BASIN OF THE LEE.

142. Present quantity flowing down the river.
143. Evidence on its capacity for increase.
144. Inference.

PAR.

SUBSIDIARY SUPPLY FROM THE CHALK.

145. Evidence on this.
146. Erroneous views.
147. Opinions of the Commission.

Summary.

148. What quantity the Thames basin will yield.

SECTION II.

AS TO QUALITY.

149. Great importance of this subject.
150. Short notice of former improvements.
151. Division of this part of the inquiry.

A.—ON THE PRESENT QUALITY OF THE WATER IN THE THAMES AND ITS TRIBUTARIES.

152. Previous analyses of the water made at various times.
153. Analyses specially made for this Commission.
154. Distinction between inorganic and organic contents.
155. Inorganic contents of Thames water.
156. Cause of hardness.

ON THE HARDNESS OF THE THAMES WATER.

157. General nature of hardness in water.
158. Dr. Clark's test.
159. Hardness of the Thames water.
160. Objections brought against the water on this ground.
161. Effects of hardness on the use of the water for various purposes.
162. General remarks of the Chemical Commission on this subject.

a. EFFECTS OF HARDNESS OF WATER FOR DRINKING PURPOSES.

163. Views of the Board of Health and of the Chemical Commission on this point.
164. Evidence given before this Commission.
165. Opinion of this Commission thereon.

b. FOR CULINARY PURPOSES.

166. Views of the Board of Health.
167. And of the Chemical Commission.
168. Evidence.
169. Opinion of this Commission.

c. FOR WASHING AND FOR MANUFACTURING PURPOSES.

170. Views of the Board of Health.
171. And of the Chemical Commission.
172. Evidence.
173. Opinion of this Commission.

OTHER ELEMENTS OF COMPARISON BETWEEN HARD AND SOFT WATERS. ACTION ON LEAD AND IRON, &C.

174. Action of soft water on lead and iron; its general solvent power. Advantage of water from the present sources in these and other particulars.

ARTIFICIAL SOFTENING.

176. Dr. Clark's softening process ; evidence thereon.
176. Opinion of the Commision.

ON THE ORGANIC IMPURITIES AND CONTAMINATION OF THE THAMES WATER.

177. Difficulty of the subject.
178. How streams become contaminated with organic matter.
179. The Thames waters are so contaminated, but in a less degree than is generally supposed.
180. Beneficial provision of nature for effecting spontaneously the purification of the streams.

Par.
181. Organic matter in water is not always prejudicial: difficulties of estimation by chemical means.

Earlier Analyses.
182. Commissions of 1828 and of 1851 : Hofmann and Blyth's ; Letheby, Odling, and Abel's; Registrar General's returns.
183. Opinions of various witnesses.

Evidence on the Organic Impurities of Thames Water.
184. By chemists and medical men.
185. By engineers and others.

Analyses of the Waters of the Thames and its Tributaries made for the Commission.
186. Remarks by Dr. Frankland and Dr. Odling.
187. Facts observed.
188. Nitrates and nitrites.
189. Organic nitrogen and carbon.
190. Effects of town drainage, and the purifying effect of the flow of the river.
191. The Thames is purer at Hampton than at any other part of its course.
192. Fluctuations in summer and winter.
193. General result of these analyses.
194. Remarks on the statements in the Registrar General's reports.

B.—ON THE FUTURE INFLUENCES LIKELY TO AFFECT THE QUALITY OF THE WATER FROM THE BASIN OF THE THAMES.

195. Probable increase of sewage from towns.
196. Treatment of this subject by the Rivers Pollution Commission.
197. Thames Conservancy Act, 1866, prohibiting the pollution of the Thames.
198. Measures taken under this Act.
199. What benefit may be expected therefrom.
200. Investigation of this by the conservancy board.
201. Evidence on the subject.
202. Investigation by this Commission of the results obtained at Croydon.

WATER FROM THE LEE VALLEY.

203. The same general remarks apply as to the Thames.
204. Report of Rivers Pollution Commission.
205. Cholera in the east of London in 1866.
206. Opinion of the Commons Committee of 1867.
207. River Lee Conservancy Act, 1868.

WATER OF THE KENT COMPANY.

208. Quality good.

FILTRATION.
209. Effectual filtration absolutely essential.
210. Made compulsory by Act of 1852.
211. Neglect of this by the companies.
212. No efficient means of enforcing it under the present system.

GENERAL REMARKS BY THE COMMISSION ON THE QUALITY OF THE WATER FROM THE THAMES BASIN.

213. Qualities of the Thames water, which render it peculiarly suitable for the supply of the metropolis.

On the Organic Impurities.
214. No evidence that the water now supplied by the companies is not generally good and wholesome.
215. Objection raised against it of a less positive character; this objection not well established.
216. Benefits to be expected from the River Conservancy Acts.

Par.
217. General opinion of the Commission.
218. Satisfactory results of the analyses made for the Commission.

PART V.

REMARKS ON VARIOUS POINTS BEARING GENERALLY ON THE SUBJECT OF THE METROPOLITAN WATER SUPPLY.

Section I.

ON THE QUANTITY OF WATER LIKELY TO BE HEREAFTER REQUIRED FOR THE SUPPLY OF THE METROPOLIS.

219. Elements entering into the consideration.

(*a.*) As to the Estimated future Population to be provided for.
220. Present population of London.
221. Views of Mr. Bateman and others
222. Explanatory diagrams.
223. Estimate by the Commission.

(*b.*) Quantity of Water to be allowed for each Individual.
224. General allowance.
225. Evidence.
226. Data as to different towns.
227. Quantity per head already supplied in London.
228. Considerations as to the future.

Estimate of Quantity.
229. Views of the Commission.

Section II.

PROVISIONS AND PROSPECTS OF THE VARIOUS COMPANIES FOR THE FUTURE.

230. Questions to the companies and their answers thereto.
231. Statements as to the various companies.
232. Summary of the whole.

Section III.

ON THE SYSTEM OF CONSTANT SERVICE AT HIGH PRESSURE.

233. Mode of distribution in London.
234. Advantages of the constant service system.
235. Difficulties that would attend its introduction in London.
236. Waterworks Clauses Act, 1847.
237. Views of the Board of Health.
238. Provisions of the Act of 1852.
239. Opinion of the Commons Committee of 1867.
240. Evidence given before the Commission.

Remarks by the Commission.
241. Constant service system ought to be introduced.
242. Difficulties under the present system.
243. How it may be effected.

Compulsory Supply to the Poor.
244. Remarks and Recommendations.

Section IV.

GENERAL CONTROL OF THE WATER SUPPLY.

245. Great importance of this question.
246. Former practice in this respect was to vest the water supply in municipal hands.
247. Evidence on the point.
248. Expediency and advantage of consolidating the water supply under public control.
249. This course the more correct on principle.
250. Compulsory rating would be necessary.

PART IV.

ON THE SUPPLY OF PROVINCIAL TOWNS.

PAR.
251. Instructions to the Commission.
252 Proceedings thereon.
253. Evidence.
254. Mr. Bateman's and Messrs. Hemans and Hassard's proposals.
255. Gathering grounds should be preserved for populations near them.
256. Groups of towns should be provided for.

SUMMARY OF CONCLUSIONS AND RECOMMENDATIONS.

PAR.
257. Conclusions and Recommendations.
258. As to the plans for obtaining water from the mountainous districts of England and Wales.
259. As to the quantity of water available from the Thames basin.
260. As to the quality of the water from the Thames basin.
261. As to the quantity of water likely to be hereafter required for the supply of the metropolis.
262. As to the system of constant service.
263. As to the general control of the water supply.
264. As to the supply of provincial towns.

REPORT.

TO THE QUEEN'S MOST EXCELLENT MAJESTY.

MAY IT PLEASE YOUR MAJESTY,

WE, the Commissioners appointed by Your Majesty for the purpose of inquiring into the means of obtaining additional supplies of unpolluted and wholesome water for the Metropolis and other large towns, humbly report to Your Majesty as follows.

1. The Commission issued by Your Majesty, and dated the 24th of December 1866, commanded us to ascertain "what supply of unpolluted and wholesome water can be "obtained by collecting and storing water in the high grounds of England and Wales, "either by the aid of natural lakes or by artificial reservoirs at a sufficient elevation "for the supply of the large towns, and to report, firstly, which of such sources are "best suited for the supply of the Metropolis and its suburbs; and, secondly, how the "supply from the remaining sources may be most beneficially distributed among the "principal towns."

A second Commission, dated the 4th April 1867, commanded us also "to inquire "into the present water supply to the Metropolis, and whether there are other "districts, in addition to the high districts of England and Wales, from which a good "supply of unpolluted and wholesome water can be obtained."

2. It will be convenient to divide our Report into six parts.

I. On the practicability of obtaining large supplies of water from the mountainous districts of England and Wales.

II. On other available sources of supply.

III. On the present Water Supply of the Metropolis.

IV. On the supply of water available from the basin of the Thames.
Section I. As to quantity.
Section II. As to quality.

V. Remarks on various points bearing generally on the subject of the Metropolitan water supply.

VI. On the supply of provincial towns.

PART I.

ON THE PRACTICABILITY OF OBTAINING LARGE SUPPLIES OF WATER FROM THE MOUNTAINOUS DISTRICTS OF ENGLAND AND WALES.

3. Our attention was first directed to the question of obtaining large supplies of water from the mountainous districts of England and Wales; and five engineering projects, having this object in view, have been laid before us.

Four of these plans have for their object the supply of the Metropolis, viz.:—

Mr. J. F. Bateman's plan, from the sources of the Severn.

Messrs. Hemans and Hassard's plan, from the lakes of Cumberland and Westmoreland.

Mr. Hamilton Fulton's plan, from the sources of the Wye.

Mr. Remington's plan, from the hills of Derbyshire.

The fifth plan, that of Mr. Dale, proposes to supply various towns in Lancashire and Yorkshire.

It will be our duty to describe these plans, and to remark on some of them at considerable length. We have caused the more important of them to be traced on the map of the rivers of England appended to this Report (Appendix B N.) which has been prepared for our use, under the direction of Colonel Sir Henry James, R.E., by the Ordnance Survey Department. From this map, on which the basins drained by the several rivers are distinguished, and many important levels given, a tolerable conception of the general form of the surface of the country can be obtained.

MR. BATEMAN'S PLAN.

4. The first on the list is that of Mr. John Frederick Bateman, F.R.S., civil engineer, who has constructed some of the largest works for Water Supply in the kingdom.

The plan proposed by this gentleman for supplying the metropolis was first published by him in a pamphlet bearing date November 1865, (which we have reprinted in Appendix E. to this Report,) and it has been more fully developed in evidence given by him before us.

App. E.

General Description of the Scheme.

5. Mr. Bateman proposes to collect water by reservoirs to be formed in the mountainous districts of North Wales, and to convey it by an artificial conduit to London.

He urges that the supply for London ought to be sought where the water is purest, softest, and most abundant, and most secure from injury by any operations of manufacture or agriculture. To obtain these conditions he has considered it necessary to go to mountains of hard and impermeable rock, where little cultivation goes on, where only a scanty population is likely to collect, and where reservoirs for storage could be easily provided. He assumes also, as a further condition, that the necessary quantity should be delivered to London at an elevation from which nearly the whole metropolis could be supplied without pumping.

He considers that the nearest high land fulfilling all these conditions is to be found in North Wales, and that the quantity of gathering ground there available is more than sufficient. He has selected, as the best, certain high drainage grounds lying to the south of Snowdon and to the east of Plynlimmon and Cader Idris, and supplying the head waters of the River Severn.

6. The map marked E (2) shows the districts referred to. The Severn rises on the east slope of Plynlimmon, and a few miles down its course it is joined by five other streams, namely, the Tylwch or Dulas, the Clywedog, the Carno, the Ceryst, and the Tarannon. Mr. Bateman proposes to combine the drainage grounds of these various streams into one district, which is tinted green on the map, and which may be distinguished as the *Southern District.* The waters from this district being collected by intercepting conduits, are to be poured into a main reservoir at Trefeglwys, subsidiary reservoirs being added in other parts of the area.

Mr. Bateman also proposes to appropriate the upper drainage grounds of two other rivers lying more to the north, namely, the Vyrnwy and Banw, whose combined waters flow into the Severn between Welshpool and Shrewsbury. This drainage ground is tinted pink on the map, and may be called the *Northern District.* Its waters are proposed to

be stored in several reservoirs constructed on the various streams, and to be collected at a point above Rhyd y Gro.

Both these districts are stated to be generally favourable for water collection. The ground lies high, the rainfall is large, and the conformation of the country admits of the construction of large reservoirs. The geological structure is favourable for the quality of the water, and Mr. Bateman gives an analysis to show that these waters are, in fact, very pure and remarkably free from mineral matter.

7. Mr. Bateman proposes to convey the water from the two districts by separate conduits, converging to a point of junction at Marten Mere, near Montgomery: from this point the joint volume of water would be conducted southwards by a common aqueduct, which, crossing the Severn near Bridgnorth, and passing near the towns of Stourbridge, Bromsgrove, Henley-in-Arden, Warwick, Banbury, Buckingham, Aylesbury, Tring, Berkhampstead, and Watford, would discharge into large reservoirs proposed to be constructed on the high land near Stanmore, about ten miles north-west of London. The total distance the water would have to be brought to London from the delivering point of either of the districts, would be a little above 180 miles. The aqueduct is designed to be capable of conveying 230,000,000 gallons per day.

The direction of the conduit is shown on the plan marked Appendix E (1), and sections of it in various places are given in the Appendices A Q and A R. It would be chiefly an open canal, lined with masonry, but it would be tunnelled where necessary through the hills, and formed by syphon pipes across the deep valleys.

The heads of the conduit, in the Welsh hills, would be at a height of about 450 feet above the mean sea level, and allowing one foot of fall per mile, the water would be delivered into the reservoirs at Stanmore at about 270 feet above the sea.

8. These reservoirs are shown on the plans marked Appendices A N (1 and 2). 6568–70.
They are designed to contain 2,000 millions of gallons, equal to twenty days' supply at the present rate of consumption.

9. The plan proposed by Mr. Bateman for the distribution of the water in the metropolis is shown on the map, Appendix A N. He would make use, as much as possible, of the existing store reservoirs of the various companies, to which he would convey the water by large main pipes from the great Stanmore reservoirs. He would, 6570–88.
however, re-arrange the distribution, dividing the metropolis into four districts, as shown on the map, conveniently arranged so as to suit the levels of the smaller reservoirs. He would further make such alterations in the service mains as would be necessary to provide for a constant service to all the houses, thus doing away with the present intermittent system.

10. Mr. Bateman states that his aqueduct, in traversing the midland counties, would 269–75.
pass within ten miles of the centre of a very populous country which is probably the most difficult to supply with water of any large manufacturing district in England—namely, Birmingham, Wolverhampton, Dudley, Walsall, and the Staffordshire coal district. He therefore thinks it would be expedient to make provision for supplying these places.

There are many important points to be considered in reference to Mr. Bateman's scheme, and on which we have received a considerable amount of evidence.

Evidence as to the Scheme.

11. With regard to the *quantity* of water which can be procured, Mr. Bateman is of opinion that no distant and expensive plan ought to be entertained which would supply less than 200,000,000 gallons a day; and he thinks such a scheme ought to be capable of further extension, so as to provide ultimately for a still larger supply.

The quantity which can be obtained depends on three elements, namely, the area of gathering ground, the rainfall, and the proportion of the latter which can be collected and stored.

12. The *area* of drainage ground marked out by Mr. Bateman is as follows:— 6561.

	Square miles.
Northern District about - - - - -	104
Southern „ „ - - - - -	100
Total - -	204

He, however, points out that this area is capable of great extension in the same basin, and that, moreover, it would be easy to add other adjacent districts of a similar character included in the basin of the Wye. The map E (2) shows the additions that may thus be made, and which comprise about 183 square miles.

13. The *rainfall* appears to be open to some doubt, no complete system of rain gauges having been kept in the district for a sufficient length of time. Mr. Bateman, therefore, in making his calculations on this point, relies to a great extent on the physical conformation of the country, and on the facts observed in nearly analogous cases.

He considers the conformation of the country favourable to a large rainfall. Taking into account the partial results noted by himself, and those obtained in places where like conditions prevail, Mr. Bateman considers that the rainfall here should be as great as in the highlands of Scotland, and as great as in the lake districts of England, with the exception possibly of a particular locality subject, from peculiar local circumstances, to an excessive amount of rain.

He considers he is justified in estimating the probable *average* rainfall in his district at about 75 inches. But as it does not do to lay out waterworks on an average, he prefers to take the two or three driest consecutive years he can find, and estimates 60 inches for them.

He then comes to the question what proportion of this is available. From long general experience and numerous observations he finds the loss, in such districts, from evaporation and absorption, vary from 9 inches to 16 inches, the smaller loss being where the rocks are the hardest and the declivities the greatest. He takes, as a safe estimate for this district, a mean of 12 inches, which, deducted from 60 inches, leaves 48 inches as the net available produce. But for greater security, he diminishes again this last result by 25 per cent., taking only 36 inches as the estimated available proportion of the rainfall on which to base his calculations. He states that this is only three inches more than he is actually collecting and storing in the Manchester Waterworks, where he supposes the rainfall is probably little more than half what it is on the Welsh hills.

From the amount of available rainfall is deducted the quantity necessary for affording compensation to the rivers. Mr. Bateman states that the compensation given in the manufacturing districts, (where frequently, in dry weather, every drop of water is impounded in the night and given out in the day,) has usually been about *one-third* of that which can be collected. But for this district he has allowed only *one-fourth*, because it is not a manufacturing district; there are comparatively no mills, and one-fourth would very materially increase the workable volume of the stream.

He remarks that the floods in these districts are enormous, being from 500 to 1,000 times greater than the dry weather flow, and it is from these that the water would be stored for the use of London, and for compensation. By impounding the water the destructive floods would be diminished and the useful volume in dry weather increased, and he adds that this has been the universal result wherever this principle has been applied.

On these grounds, Mr. Bateman arrives at the following quantities:

	Northern District.	Southern District.
Amount estimated at a rainfall of 36 inches, about	148,000,000	144,000,000
Deduct one quarter for compensation for rivers -	37,000,000	36,000,000
Leaving for the available supply - - -	111,000,000	108,000,000

giving about 219,000,000 gallons per day as the gross produce of the two districts, having the areas above stated. But from the facility of increase of area, he has not hesitated, in his subsequent calculations, to assume an available quantity of 300 millions of gallons.

14. Other authorities, whom we have examined, think Mr. Bateman's estimate of quantity and rainfall too high.

Mr. Hawksley, also a civil engineer of great experience in water supply, judging by analogous districts, considers that the average rainfall would not exceed 45 inches over the whole surface. But he remarks it is known to be impossible, by any system of reservoirs that can be constructed, even with large capital, to deal with more than the average of three consecutive years of minimum fall; the minimum year has about one-

third less than the general average, and in the three consecutive driest years the average fall is almost precisely one-sixth less. Hence, deducting one-sixth from 45 inches, there remains 37½ inches, which Mr. Hawksley considers the quantity due to the three minimum years. Then, secondly, the loss by evaporation, &c. over a district like that, part of which is lowland and part highland, he estimates at about 13½ inches, which leaves 24 inches as the quantity of rainfall available, instead of 36 inches as estimated by Mr. Bateman.

Mr. G. J. Symons, who has for several years recorded annually (in a work published by him entitled "British Rainfall") the fall of rain in various parts of the kingdom, and who has given us elaborate evidence bearing on this and other plans, infers from the facts at his disposal, that the mean fall in three successive dry years would be 44 or 45 inches. 467–506. 526–45. 2729–30.

The Rev. J. C. Clutterbuck doubts Mr. Bateman's estimate of rainfall, and considers the gaugings of the rivers form the only safe criterion of the amount of water obtainable. 1848–66.

Mr. Rawlinson, civil engineer, believes averages in this respect delusive, and considers that a deduction of one-third should be made from the average, to give the minimum fall. 1427–40.

Mr. Hassard, civil engineer, considers that the conclusions which Mr. Bateman has arrived at from the result of gauges kept during the three wettest months of an exceptionally wet year, are not in accordance with the results of gauges in the immediate locality relative to the fall of three dry years. He is of opinion that a greater rainfall than 42 inches could not be reckoned upon over that drainage area in three successive dry years. 965–78.

Mr. Bateman's answers to these objections may be seen in his evidence. 6485. 6524–39.

15. The *storage* is a matter of much importance, as affecting the quantity of water which can be made available to send off the ground. This storage must be sufficient in capacity to collect and impound the flood waters during heavy rains, so as not only to provide sufficient supplies in the dry portions of the year, but also, to a certain extent, to equalize the product of wet and dry years. The storage room must further be calculated not only for the quantity of water intended to be conveyed away, but also for the additional quantity to be sent down the rivers as compensation. 6615.

There being no natural lakes in the district, Mr. Bateman is obliged to have recourse to the formation of reservoirs on a large scale. App. E. 6513–5.

For reasons given by him he considers that a provision for 120 to 140 days' supply would be sufficient, and on this assumption he proposes to make the following reservoirs:— 6560–63. App. E. 37–52. 109–15.

Northern District.	Cubic feet.
Four reservoirs, total capacity about - -	3,494,000,000.
Southern District.	
Three reservoirs - - - - -	3,215,000,000.

The sites of these will be seen on the map E (2), and further particulars will be found in Appendix E., and in Mr. Bateman's evidence. He states that none of the embankments would be more than 80 feet in height, and they would be placed in situations where either hard impervious clay or the solid rock of the Silurian formation would afford the means of making them perfectly safe and water-tight. Two of these reservoirs would be some miles in length, and one, with an embankment of 75 feet high, would hold 50 per cent. more than the available water of Loch Katrine.

16. Some objections have been brought against this portion of Mr. Bateman's plan. Mr. Hawksley considers the proposed storage insufficient, and that the reservoirs, to provide for the three driest years, ought to store about 170 days' supply. 2483. 2489.

Objections have also been made to the amount of property which must be sacrificed to form the reservoirs, and to the danger which might be apprehended in the valley of the Severn from any accident happening to artificial reservoirs, at such an elevation, and containing such an immense storage of water.

17. Another point of great importance in Mr. Bateman's scheme is the *quality* of the water which it will afford.

He has laid before us some analyses procured by him of samples collected in the district; but as we felt that this was a matter on which it was desirable to have the most positive and unexceptionable data, we determined, with the sanction of the Lords of Your Majesty's Treasury, to carry out an independent investigation, by having the district examined, and samples collected and analysed, by competent persons under our own direction.

It was important, in the first place, that the district should be examined, and the samples collected, by a person accustomed to such matters, and this duty we intrusted to Mr. W. Pole, F.R.S., a civil engineer of experience in water supply. He was instructed to go over the ground and select points where samples might be taken, so as to give a fair idea of the waters of the district; to take such samples and forward them to the chemists for analysis; and to note any observations as to the district generally which might appear worthy of our attention. Mr. Pole's report will be found in Appendix B.

Fourteen samples of water were taken, in different parts of the district, and were submitted for analysis to two chemists of eminence, Dr. Frankland, F.R.S., who is employed by the Registrar General to analyse the metropolitan waters, and Dr. Odling, F.R.S., Professor of Chemistry at St. Bartholomew's Hospital. Their report will be found in Appendix D.

18. The quality of water afforded by any particular gathering ground will depend, in the first place, on the geological structure and mineralogical composition of the rocks; in the second place, on the nature of the surface; and thirdly, on the population, cultivation, and on any accidental circumstances that may affect its purity.

To illustrate the geological and physical features of Mr. Bateman's gathering ground we have caused to be prepared the two maps marked Appendices B A, 1 and 2, the former showing the geology of the district, the latter the elevations of the ground expressed by contour lines. The geological and mineralogical features are favourable; the rocks (almost entirely slates of the Silurian series) are such as are best adapted to preserve the purity of the water falling on them, being practically insoluble, and very little liable to disintegration.

The nature of the surface varies in different parts. In the higher portions it is hilly and steep, the slopes are covered with grass used for cattle and sheep pasture, and the population is very scanty. In descending the valleys cultivation begins, trees appear, and the population increases; while in the lower and flatter parts of the district the land is fertile and well tilled. The latter, however, forms only a small portion of the district, and there is no population beyond that of small villages included in the drainage area.

App. D. 6200-6432. 6433-6484.

19. The analysis of the Welsh waters bears out the anticipation of their quality that might be formed *à priori*, and gives the following results: The quantity of solid contents is very small, varying over the district generally from about $2\frac{1}{4}$ to $4\frac{1}{2}$ grains in the gallon. The waters are extremely soft, their hardness, according to Dr. Clark's test, being generally only 1 or 2 degrees. The organic matter is also small, and there are no traces of any noxious pollution; and so far as could be judged by the samples collected, they were of fair appearance, taste, and aëration.

Mr. Bateman asserts that the water will require no filtration, as the storage in such large reservoirs will sufficiently clear it. He bases this opinion on the general clearness of water in natural lakes.

20. We may briefly allude to five objections which have been made to the Welsh waters on the ground of quality.

The first is to the amount of cultivated land in the lower portions of the district, the manuring of which must, it is said, pollute the water flowing over it. But the analyses do not detect any noxious pollution.

App. B.

21. The second objection is the existence of certain manufactories, the refuse of which is calculated to defile the water. This objection has been examined by Mr. Pole on the ground, and shown to be quite insignificant.

22 The third objection is that the district contains metalliferous veins and mineral workings, principally lead, which, it is urged, must contaminate the streams. This is, at first sight, a formidable objection, on account of the well-known powerful effect of many metallic salts upon the human system. On this account we directed Mr. Pole carefully to examine the facts upon the ground, and his full report on the subject, conjoined with the analysis of the samples he brought away for the purpose, disposes we think effectually of this objection. It is true that there are lead workings in the southern district, and that from many of them suspicious-looking refuse is turned into the streams; but it is found that this refuse contains as a rule no metallic salts soluble in water, and consists only of a detritus formed from the earthy matrix of the ore, generally finely divided quartz or slate, which has been separated by the grinding and washing processes, and is held in

App. B. App. D. 8213-4.

mechanical suspension by the water passing away. This, if admitted into the reservoirs, would soon deposit and leave no pollution in the water; Dr. Frankland even suggests that its presence might be useful, by carrying down organic matter in the process of deposit. Mr. Pole points out that it might be easily prevented from fouling the streams.

23. The fourth objection is in regard to the existence of peat, and its influence on the water. There is a tendency for peat mosses to form and accumulate in mountainous districts, and the brown colour they impart, under certain conditions, to the water issuing from them, is well known. Mr. Pole remarks that in the higher parts of this district patches of peat moss were of frequent occurrence, and that beds of peat of considerable extent were cut and used generally in the neighbourhood for fuel. We believe it is found that in dry weather the streams of such districts, being the produce of springs, remain clear, not taking the peaty tinge; but that in rainy weather, and flood times, when the water permeates and drains through the mosses, an objectionable colouring effect occurs. The majority of the samples collected for the Commission were taken in fine weather, and are reported as clear; but one or two exceptional samples procured during partial floods were highly coloured, being reported as "deep yellow" after standing two days, and leaving a very brown residue on evaporation. App. D. 6203.

Mr. Bateman, from his experience of Loch Katrine, believes that the brown colour of peaty water is lost by exposure to the atmosphere, and argues that the effect of the storage in large reservoirs, and the passage through the long conduit, would have the effect of delivering the water in London perfectly colourless. He has also described to us an ingenious arrangement in the Manchester Waterworks, by which the colourless dry weather discharge of certain streams is separated from the peaty water of floods; but the applicability of this system on so extensive a scale as that necessary for the London supply has been questioned by other witnesses. 134–6. 6657–62. 2510.

Dr. Angus Smith thinks it might be necessary to remove the colour by filtration, but is in doubt how to apply the process. He thinks it cannot always be drunk with impunity, but the only points requiring much attention are the bitter taste and the appearance. 7264. 7214–55.

Dr. Frankland says that the ordinary sand filtration will not remove the colour, and suggests the use of animal charcoal; but he agrees with Mr. Bateman, that by storage in large reservoirs much of the peaty matter would, in all probability, be precipitated. 6203-12.

Dr. Miller thinks peaty water would not be injurious to health, but describes it as at times very disagreeable for drinking purposes. 7059–7124.

Mr. Hawksley is of opinion that in the metropolis it is very necessary that the water should be white water, perfectly clear and colourless, because coloured water would be disagreeable and contrary to the taste of the people. He says soft water is almost necessarily tinted, as it generally comes from moors and from elevated mountain districts, on which there is a large quantity of peat growing, and it is almost impossible to prevent that water acquiring a stain more or less deep. In dry seasons water from these districts may be a good colour, but it is coloured during floods, and these form the great bulk of the supply. 2504–9.

Being asked, If he could choose between the present and soft water for the London supply, which he would prefer? he says, if he could get the water tolerably free from stain he would use the soft water, but if not he would most certainly prefer the white water. He says that peaty water would not be tolerated in London, and instances that its introduction into Liverpool has given rise to much dissatisfaction. Manufacturing towns choose soft water, even if brown, on account of its importance to their trade; but generally, for drinking purposes, the clear, bright, sparkling water is preferred.

Dr. Letheby also states the water from peaty districts would be so frequently tainted and coloured that it would be objectionable, and that Londoners would not drink it. They would prefer a clear, pure, chalk water. 3870–2.

Mr. Simpson objects to the peaty tinge of water brought from certain hilly districts. He says:—"The Severn water at certain seasons is brown as coffee, and it is not a pleasant "water to drink," and he alludes to the colour of the water at Manchester and Liverpool, corroborating Mr. Hawksley, that at the latter place there was a great complaint on this ground. 4685.

24. The fifth objection is one often brought against soft waters, namely, the facility with which they often act on lead.

Drs. Frankland and Odling consider that soft waters do not necessarily act on even bright lead, and that on tarnished lead they seldom act at all. App. D.

1491–8. Professor Way considers that if soft water were used, it would be prudent to guard against its action on lead, by substituting iron for lead pipes.

2671. Dr. Lyon Playfair states that on the intermittent system of supply, with the pipes alternately full and empty, soft water may act upon the lead of the pipes; but if the pipes were always full, as on the constant supply system, there would be very little or almost no risk.

3140–2. Dr. Parkes considers that it would be hazardous if means were not taken to secure the pipes against the action of soft water.

The evidence does not show any instance of injurious effects having resulted from the introduction of soft water into Manchester, Whitehaven, and other towns.

6616. 25. On the important question of cost Mr. Bateman has given us estimates prepared in great detail, having reference to a supply of 230,000,000 gallons per day; but in order to make the outlay gradual, he proposes to divide the execution into four progressive stages, giving—

	Galls. per day.
For the first stage - - - - -	130,000,000
„ second „ - - - - -	170,000,000
„ third „ - - - - -	200,000,000
„ fourth „ - - - - -	230,000,000

The estimates of outlay on the new works for these several stages, including interest on capital expended during the construction of the works, are as follows:—

For the first stage - - - - -	£8,685,006
„ second „ - - - - -	10,571,615
„ third „ - - - - -	10,822,474
„ whole ultimate supply of 230,000,000 gallons per day	11,400,023

These sums include the necessary arrangements for conveying the new supplies to the existing reservoirs, with a view to their distribution by the existing mains, but do not include the purchase of existing works or interests. Mr. Bateman, however, estimates that certain property of the companies, to the value of 1,000,000*l.*, may be disposed of as soon as the supply by gravitation is introduced; and he therefore deducts this, reducing each of the above amounts by that sum.

App. E. 6738–44. 26. Mr. Bateman uses arguments to justify the expediency of such a large outlay for the water supply of London as his scheme would involve. He says, "The amount of "the estimate need not startle the public, for it is not more in proportion, either to the "quantity of water to be obtained, or the ability of the inhabitants to pay for it, than "has been expended in Glasgow, Manchester, Liverpool, and many other towns, while "it is far below the cost incurred by many other towns which could be mentioned."

He gives the following comparative statement of the outlay actually incurred in several large towns for bringing improved supplies of water, including compensation to old companies:—

	Cost for each million of gallons per day.
Liverpool - - - - - - - -	£120,606
Glasgow, for limited supply - - - -	59,200
Do., for full supply - - - -	33,645
Manchester - - - - - -	60,000
London, estimated outlay for limited supply of 130,000,000 gallons -	£165,416
Do., for full supply of 230,000,000 gallons - - -	100,454

But Mr. Bateman considers a fairer test of the ability to pay for water is found in the *assessable value* of respective places, and he gives the following data, calculated in 1865, since which time, however, the rateable value in London has much increased:—

	Total assessable Value.	Assessable Value for Dwelling Houses.
	£	£
Glasgow - - - - -	1,200,000	600,000
Manchester - - - - -	1,200,000	600,000
London - - - - -	15,000,000	10,000,000

From this he reasons that London could bear an outlay for waterworks twelve times as great as Manchester and Glasgow, if measured by the total assessable value, or sixteen times as great if measured by the assessment on dwelling houses alone. And as the outlay in each of the two smaller cities has been something more than 1,500,000*l.*, the proportionate outlay for London would be 19,000,000*l.* on the first principle, and 25,000,000*l.* on the second.

27. Mr. Hawksley doubts the sufficiency of Mr. Bateman's estimate, believing that his reservoirs must be increased in capacity, as before stated.

28. Mr. Bateman developes a financial plan by which he conceives the scheme could be economically carried out, namely, by following the example of the two towns mentioned. App. E.

In each of these towns the waterworks are the property of the corporation, who have the power to levy two rates on account of the water supply, viz.:—

1. A *public rate*, levied in consideration of the protection against fire which "constant supply" and "high pressure" necessarily confer, and in consideration also of the great advantage which all property is supposed to derive from a full supply of water.
2. A *domestic rate*, in respect of the water supplied for domestic purposes.

Both these rates are compulsory rates, levied on all parties, whether they take the water or not. The amounts actually levied at present are:—

	Public Rate.	Domestic Rate.
	In the Pound.	In the Pound.
In Glasgow - - - - -	1*d.*	1*s.* 0*d.*
In Manchester - - - - -	3*d.*	9*d.*
In Liverpool - - - - -	6*d.*	4½*d.*

Mr. Bateman proposes that the water supply of the metropolis should be vested in a public body, who should have power to levy rates of this kind, and who would then proceed to purchase the interests of the several existing water companies, and to introduce the new supply.

29. Mr. Bateman explains that he has been led to the projection of his gigantic scheme by the analogy of the works he has carried out for supplying Glasgow with water from Loch Katrine. For many years the inhabitants of that city, who had previously drawn their supplies from the Clyde, had become uneasy as to the quality of the water, and had anxiously sought for purer sources. In 1853 Mr. Bateman proposed to supply the city by water collected in Loch Katrine, and brought to Glasgow by a conduit 35 miles long. The proposal was at first startling by its magnitude, but after much discussion it was sanctioned and carried out, and the water was delivered from the new source in 1859. Various particulars will be found in the drawing, Appendix A O. 146–58. 176–86.

Emboldened by the success of this work, and acting on the assumption that the metropolis is, or soon will be, in a similar difficulty to Glasgow as regards the supply from its natural river, Mr. Bateman has now brought forward this still bolder scheme. He has sought about, he says, in all directions for a suitable source of supply, and believes that the district he has chosen possesses greater advantages than any other. We may conclude our description with his own words on this point. He says:—

"I may say that I selected this district with a perfect knowledge of what every other part of the country could do. I was aware of the vast quantity of water, and about which there can be no kind of question, in the Lake district, and the elevation of the Lakes; and I knew that those lakes from which water could be obtained were not higher than the sites of reservoirs, which could be formed just as large as lakes, and better than lakes, because you could make them hold more water in the same area in the Welsh hills. Therefore, not only with reference to distance, but with reference to inclination, it was most important to get the water which you wanted at the nearest point. The backbone of England is not only now largely drawn upon by a great many large towns on both sides, in Yorkshire and Lancashire, but it neither possesses the facility for constructing reservoirs, nor the vast amount of rainfall, nor the large area of drainage which for the metropolis is necessary, nor ought it to be tapped, because it is, in fact, the natural resource of all the manufacturing towns in Lancashire and Yorkshire and Cheshire, and therefore the Derbyshire hills and Yorkshire hills were out of the question. The only two districts from which water could be derived were the English lakes and the Welsh hills, without interfering with what might be considered in a national point of view the property 158.

of other districts. But the English lakes, at no greater elevation than the Welsh hills, were at twice the distance, or nearly so.

* * * * * * * * * *

A consideration of all these circumstances (and I gave the whole subject full consideration) determined me in going to the Welsh hills. I saw that there you could get everything nearer, and at an elevation which would enable you to make the works cheaper than in any other part of the kingdom."

Remarks by the Commission on Mr. Bateman's Plan.

30. Having now described the main features of Mr. Bateman's scheme, as presented to us, we proceed to offer some remarks upon it.

31. We are of opinion that Mr. Bateman's plan is practicable in an engineering point of view. The construction of large reservoirs, and the formation of a long conduit, present no problems beyond the ordinary resources of engineering skill, and there are no local or other difficulties to be contended with but such as must be expected to attend works on such a large scale, and such as may with ordinary prudence be surmounted.

32. With reference to the estimates of the cost of these works, as laid before us by Mr. Bateman, we must remark that although he has taken great pains to ascertain the main features of the scheme, sufficiently to establish its practicability, and in some cases by actual survey, yet that detailed surveys and sections of the greater part of the works (the cost of which surveys would probably be not less than 10,000*l.*) have not yet been made. In the absence of such detailed surveys of a scheme involving works of great magnitude, and to some extent novel, and subject to large contingencies and elements of uncertainty, we do not consider that it is possible to arrive at any reliable estimate of the cost which could safely be taken as the basis for recommendation of the scheme.

33. Mr. Bateman, in answer to question No. 6740, has given a calculation of the expected annual income and expenditure, but we are satisfied that there are many points in this calculation which are open to objection or doubt, and we are not able to adopt it.

34. He has also, in answer to question No. 6632, given, in a tabular form, "comparative "estimates of obtaining additional supplies of water from the existing sources and North "Wales," but on examination of the details of these calculations we are of opinion that these estimates are equally open to objections, and Mr. Bateman has not convinced us of the superior economy of the Welsh scheme. He contemplates considerable saving from the consolidation of the management, and from the levying of compulsory rates; but these measures would be equally applicable, and the benefits arising from them equally available, if the present sources of supply were retained.

35. It must be recollected that Mr. Bateman, if his gravitation scheme were introduced, could not entirely dispense with pumping. The high-water level of his Stanmore reservoirs, though 270 feet above ordnance datum, would be less than 200 feet above the ground level of many populous parts of London. And considering the depths to which both the Stanmore and the district reservoirs must of necessity occasionally be drawn down, and the large pressure necessary to force the water through the main and distributory pipes, we doubt whether the head would be sufficient to supply the upper stories of the houses in many parts of London, particularly under the unequal drafts resulting from the system of constant supply. In all these places, therefore, pumping would be required, and this would diminish the advantage assumed for the gravitation scheme.

36. The quality of the water, which appears very similar to that supplied to Glasgow from Loch Katrine, is satisfactory as regards its softness and purity. On other points we consider there are objections.

In the first place it is liable to be coloured by peat. The evidence shows the large presence of peaty matter in the flood samples, and as the great body of the water collected would be in floods and rainy seasons, there seems reason to believe that the coloured condition would be a common one. We agree with the witnesses that coloured water would not be acceptable to the inhabitants of London, for a taint in the water which is visible to every drinker is more likely to be objected to than one which might perhaps be less harmless but less easily seen. We think the question of how far the colour would be lost by storage and in the conduit requires determination by more extended experience;

and it is obvious that the adoption of any system of filtration, if applicable in such a case, would add largely to the original outlay, as well as to the annual cost of the supply.

There is another point requiring serious consideration, namely, the action of soft water on lead, which is often energetic. Of the sixteen samples of Welsh waters collected for the Commission by Mr. Pole, nine were found to act more or less on bright lead, and five to have no action; while on tarnished lead two had considerable action and fourteen had no action. It is true that the introduction of soft water into towns has in this respect often been effected with apparent impunity. The pipes and cisterns soon become coated in a way that, if they are kept full, is thought to preserve them from chemical action. We are, however, told by a very competent witness, that in Manchester "there have been 7268.
"several instances where medical men have believed injurious effects to have been caused "by the lead, and in several cases where there have been lead cisterns the effect has been "very decided indeed; but there have been also several where it has been believed that "the lead poisoning had its origin from the pipes alone,—enough at least to render great "caution necessary." We have had it also stated "that soft waters do not *necessarily* "act on lead." Although, therefore, under a perfectly efficient system of management, or by the substitution of iron for lead, there may be little danger to be apprehended from the use of soft water, still, under the innumerable accidental conditions which must occur in the distribution of a large town supply, arising from repairs of pipes, leakages, carelessness, peculiar states of the water resulting from local causes, and so on, there is no doubt that whilst in hard water the risk of danger is reduced to a minimum, in soft water, on the contrary, the risk must be a maximum one, and one which must always exist.

The circumstance that generally no ill effects have been found to result from the introduction of soft water, is inconclusive against the instance in which it has been affirmed; and unless a very clear and serious case were to occur, many minor cases of slight injury might take place without the cause being suspected.

We shall make some further remarks on the comparative advantages and disadvantages of hard and soft water in a subsequent part of our Report.

37. There is at present an insufficiency of data as to the amount of rainfall in the district, but we are of opinion that the evidence before us tends to show that Mr. Bateman's estimate of it is too high. The rainfall in all districts varies very much in different years, as well as in different parts of the same district, and hence it is only by a long continued and widely extended series of observations on the ground itself that any exact results can be obtained.

Although Mr. Bateman's anticipations on this point may not be fully realized, it must 6701–2.
be borne in mind that he states such a deficiency may be met by taking in a larger area of gathering ground. This appears feasible, the drawback being that it would increase the outlay necessary to be expended.

38. There is every reason to believe that if Mr. Bateman's scheme were ever brought forward in Parliament, it would be subject to a most powerful and determined opposition from interests of various kinds connected with the river and estuary of the Severn.

The Commission has received little or no evidence on this head; for the reason, no doubt, that until the scheme assumes a more practical shape, there is not sufficient inducement to the various parties to come forward.

Mr. Hawksley alludes to some of the points that would be likely to come into dispute, 2460–4.
stating that there are very large interests down the River Severn, from its head to the foot of the estuary, which will be interfered with.

Mr. Simpson corroborates this, and adds that the abstraction of water would be a serious evil, and that considering the great trade and the sums of money that have been spent on the river, it is questionable whether it ought to be interfered with.

It has also been objected that the appropriation of the streams and the loss of the floods would destroy or injure valuable fisheries, particularly of salmon; but on this point we have had no evidence, no one interested in these fisheries having appeared before us.

39. A serious objection has been raised to this as well as to other large schemes for supplying the metropolis from a distance, namely, the danger of having so large a population as that of London and the suburbs dependent solely on one supply of water, which might so easily be stopped by any one of several causes, such as wilful damage, frost, or the failure of any work along the line.

In regard to the first of these causes, we believe anxiety has been felt in other analogous cases. Mr. Hawksley says that this objection has been practically raised by foreign Governments to schemes of his own under similar circumstances.

2527–8.

Mr. Duncan testifies to the anxiety lately felt on this point at Liverpool, and the precautions taken there to prevent interference with the works.

2422–8.

Mr. Hawksley also attaches much importance to the difficulties likely to arise in long-continued cold weather, from frost and snow impeding the current through the long open conduits; and Mr. Muir, the engineer to the New River Company, states that it requires labour and considerable expense in severe frost to keep the New River in efficient flow.

2527–43.

3990–8.

Mr. Bateman, in reply to these objections, says he has provided for ordinary cases of interruption by reservoirs of so large a size near London, that within 10 miles there would be three weeks' storage to cover any interruption from accident or repair. He admits that no provision could be made against the possibility of the water being cut off during hostile occupation or by wilful damage; but this objection is, Mr. Bateman considers, applicable to many large cities; and is a contingency so remote as not to weigh against the many advantages of the plan.

6570.
6643–4.
240–43.

His experience of Loch Katrine aqueduct leads him to attach no great weight to the objection as to freezing, as in a very severe winter, when the temperature fell to 12 and 14 degrees below zero in the open air in the district along which the conduit was carried, the temperature of the Loch Katrine water never fell lower than 39 degrees, and there was not a particle of ice in any shallow or bay in Loch Katrine.

6669–79.

We do not, however, consider the two cases analogous. The great depth of Loch Katrine may maintain a minimum temperature of 39°, but in smaller reservoirs the temperature would necessarily be liable to fall lower. Further, the water after leaving Loch Katrine, having to pass through a tunnel 2,325 yards in length and in places 523 feet below the surface of the ground, and again just before reaching Glasgow passing through another tunnel of 2,640 yards long and 246 feet below the surface, would necessarily have its temperature raised in winter in consequence of the permanent greater heat of the ground at those depths. In the Welsh scheme, on the contrary, there are no deep tunnels; and whereas in the Glasgow works the whole distance of 26 miles was tunnelling or "cut and cover," here there would be nearly 100 miles of open cutting In a river like the Thames the temperature in winter is kept up by the springs which feed it, an advantage an aqueduct does not possess.

The freezing of canals and rivers, even of considerable capacity, in this climate, is a matter of frequent occurrence; and it must be borne in mind that, although the channel may not actually be stopped, the presence of ice and congealed snow in it would seriously diminish the velocity of flow and consequently reduce the quantity of water conveyed.

Then in a conduit of such vast length, and involving engineering works of such great variety and magnitude, it is only reasonable to contemplate the possibility that by some unavoidable mischance, such as a landslip or otherwise, failure or accident might happen to some of the works, which might have the result of stopping the flow for perhaps a considerable time; and in case of repairs being necessary it must be remembered that a large river 180 miles long, with a considerable fall and velocity, would be a difficult thing to deal with.

40. The objection as to the danger of the collection of such vast bodies of water in artificial reservoirs at the head of so important and populous a valley as that of the Severn, derives its principal force from the accidents that have been known to arise, and the destruction of life and property that has ensued from the rupture of reservoirs. And, considering that several large towns and populous and flourishing districts, would all be at the mercy of a flood from one of these gigantic stores of water, and that any failure would be most likely to happen when the store was at the largest, there is no doubt that an accident of the kind would be a great national disaster. In the hands of competent engineers and contractors, with ample funds and time at their disposal, the works may be so substantially constructed as to reduce the risk of such accidents to a remote chance, but we think that, although such an objection ought not to weigh against the plan if it were necessary, it may form an element in the choice between this and other sources of supply.

THE CUMBERLAND LAKE SCHEME.

41. Another plan, somewhat similar to that last described, is brought forward by Messrs. Hemans and Hassard, who propose to supply the metropolis with water from the lakes of Cumberland and Westmoreland.

This plan is described in a pamphlet published by the promoters in July 1866, which we have reprinted in Appendix F., and we have had explanations given by both these gentlemen in their examinations before us.

42. They remark, "It is felt that these suggestions appear somewhat at a disadvantage, App. F.
"particularly as the sources of water supply recommended would seem at first sight to
"demand works in length and extent of greater and more startling magnitude than even
"the already sufficiently bold project of Mr. Bateman, for bringing water to London from
"the Welsh hills at a distance of 183 miles. The sources herein recommended lie at a
"distance of 240 miles from London, but, notwithstanding this increase of distance, we
"believe that when the subject is fully investigated it will appear that our project—
"although involving an apparently larger outlay in the first instance—will, from the
"absolute certainty of the rainfall, the extraordinary purity of the water, the facilities
"afforded by the existing lakes for the construction of the immense reservoirs, and from
"the revenue which may fairly be expected from the sale of water in the districts
"traversed by the aqueduct, be found the best and cheapest which has yet been proposed,
"and that ultimate economy will arise from its selection."

43. The scheme is somewhat complicated in its arrangement, but it will be easily understood from the map, Appendix F (1).

It will be seen that to the north of the great dividing range of hills running east and west between Scaw and Shap fells lie three large lakes, Thirlmere, Ullswater, and Haweswater. These are at a considerable altitude, the level of the water above the sea in each lake being as follows:—

	Feet.
Thirlmere - - - - - -	533
Ullswater - - - - - -	480
Haweswater - - - - - -	694

It is proposed to dam up the outlets of the two higher lakes, so as to raise their levels still further, namely, Thirlmere by 64 feet, and Haweswater by 42 feet.

It is also intended to increase the quantity of water running into them by adding the drainage from the sides of neighbouring hills, to be collected and brought into the lakes by intercepting conduits at proper levels.

The waters from these two lakes would then be conducted by conduits and tunnels into the centre or lower lake, Ullswater, which would be treated as a great distributing reservoir from which the supply would be drawn off as required. This lake has a large drainage of its own, and it is proposed to increase it by a small additional district in the same way as the others.

The natural outlet of the Ullswater lake is at the north end, by the River Eamont, flowing into the Eden, and so by Carlisle into the sea. It is proposed, however, in the present scheme, to tap the lake at its southern end, and to run the water off from it by a tunnel to be formed under Kirkstone Pass, opening out on the slopes of the hills above Windermere, from whence the water would flow by gravitation through a conduit to London.

44. *Area of the Districts.*—The area of the district proposed to be made available as collecting ground is as follows:— App. F. 1.

	Square Miles.
Thirlmere drainage - - - - -	44
Haweswater „ - - - - -	38
Ullswater „ - - - - -	95
Total	177

To this may be hereafter added—

Drainage on the southern slopes of the main range -	53

App. F. 45. *Rainfall and Quantity of Water.*—The lake district having been long noted for its large rainfall, the promoters consider that on this point no difference of opinion can arise.

In the pamphlet (Appendix F.) the promoters state that the observations of the late Dr. Miller, from 1847 to 1853 inclusive, give an average annual fall of 100·56 inches, but 1864 and 1865 being dry years gave only 80·38 inches. They therefore, to avoid question, took the smaller figure 80 inches as the rainfall to be depended on.

606–23. Mr. Hassard, however, in his evidence gives a revised estimate. He says that the three years 1853, 1854, and 1855 were consecutive years of very great drought, the quantity being only about 83 per cent. of the average. These three years give a mean of 64 inches, which therefore he takes as his standard of estimation.

App. F. From the rainfall has to be deducted the loss by evaporation and absorption, which, in a precipitous and rocky district, the promoters assume will be not more than 12 inches. They, however, take it as 14 inches.

The following therefore appears to be their estimate of the quantity to be yielded by the district:—

Area of collecting ground	177	sq. miles.
Mean rainfall of three consecutive dry years	64	inches.
612. Deduct loss by evaporation and absorption	14	„
Available	50	„
This from a drainage area of 177 square miles will give per day about	350,000,000	gallons.
706. Deduct for compensation to rivers a quantity equal to 9 inches of rain over the collecting area	63,000,000	„
Available for supply to metropolis and other towns	287,000,000	„

Mr. G. J. Symons has given us an elaborate report on the rainfall. He considers the evidence in regard to the lake district unusually complete; and he infers from the whole that the true mean rainfall for it may be taken at 77 inches, and the mean of three dry years at 80 per cent. of this, or 61·6 inches. In the driest years he would take something like 66 or 68 per cent. of the average, which would give about 53 inches. During the ten years ending 1859 there was only one drought of more than 40 days' duration, and more than one inch of rain fell during its continuance.

46. *Storage.*—The storage would be obtained principally in Ullswater, Thirlmere, and Haweswater lakes, but partly also from auxiliary reservoirs formed in other places; the raising of Thirlmere and Haweswater, as already described, would allow of a large amount of storage room in them. It is also proposed to raise Ullswater 5 feet, and to draw it down 20 feet when absolutely necessary. It is explained, however, that this would only be required when the maximum quantity was taken, and even then only in very rare cases of extreme drought.

The whole available storage would be about 5,563,000,000 cubic feet, which is equal to 120 days' supply at 250 millions of gallons, or to 157 days' supply at 200,000,000 gallons per day, after giving credit for the average minimum summer yield, and allowing for compensation.

App. F. 47. *Conduit.*—The water would be conveyed from Ullswater to London over a length of 270 miles by conduits, tunnels, and iron pipes.

The work of greatest magnitude connected with the scheme would be the tunnel under Kirkstone Pass, to bring the water southwards from Ullswater. It would be 7¼ miles in length. From the south end of this tunnel the conduit would pass by Ambleside and Kendal, and down the eastern side of Lancashire (avoiding the Wigan coalfield), to the east of Manchester and of the Potteries district, and to the east of the Staffordshire coalfield and of Birmingham, and onwards towards London, following a route
301–2. nearly parallel with that of the London and North-western Railway. The conduit would be in effect equivalent to a river 30 feet wide and 10 feet deep. The inclination taken has
428. been small, viz., 6 inches, and in some cases 4 inches per mile, and for pipes 20 to 24 inches per mile. Probably in some part wrought-iron pipes of 8 feet diameter, lined with cement,

might be used with advantage. Detailed descriptions of these works, and of the nature of the districts over which they are taken, will be found in Mr. Hassard's evidence. The conduit would terminate in a large regulating reservoir to be constructed near Edgeware, at a distance of about 12 miles from Cumberland Gate, Hyde Park. The height of this would be 232½ feet above Ordnance datum, which the promoters consider would ensure an ample pressure for ordinary domestic supply and in case of fire, and would allow of the use of the existing appliances of distribution, which they assume would be destroyed by the use of a much higher pressure and by the adoption of a different system of service. Elevated districts must still be supplied by pumping. The reservoirs are proposed to be in duplicate, containing in the aggregate 15 days' supply at 250,000,000 gallons per day. 733. 743. 730–57. 765–7. 778–817. 823–38. 818–22.

48. *Other Towns on the Way.*—The promoters state that the conduit, in passing through the heart of England, Lancashire, the Potteries, and the midland counties, would be capable of affording *in transitû* a practically unlimited supply of water to the large manufacturing districts and population on the line of its route. They estimate that more than 50,000,000 gallons per day might thus be disposed of.

49. *Additional Supply from Bala Lake.*—The promoters contemplate taking in water from Bala lake, in order to replace water which might be sold to manufacturing towns in the north. This would require an additional aqueduct 70 miles in length, which would join the main conduit at Stoke; and at the point of junction they propose to form an additional reservoir capable of holding about 21 days' supply; they estimate the cost of this addition at 1,500,000*l.*, and the extra quantity obtained at from 50,000,000 to 60,000,000 gallons. 589–604. 884–98.

50. *Estimate.*—The promoters estimated in their pamphlet that the cost of the project complete, for 250,000,000 gallons a day, would be 12,200,000*l.* But in Mr. Hassard's evidence he gives an amended estimate as follows:— App. F. 1060.

Reservoirs, conduits, and works of collection -	£1,013,000
Tunnel under Kirkstone Pass - - -	360,000
Aqueduct to London - - - -	9,806,260
Regulating reservoirs near London - - -	500,000
	£11,679,260
Interest during construction, and other expenses -	1,820,740
	£13,500,000

Mr. Hassard compares this estimate with that for Mr. Bateman's plan, and also with the cost expended for a like purpose in Liverpool, Manchester, and Glasgow, and gives the result as follows, being the cost for each million gallons per day:— 681. 693–9. 718–28. 839–51. 1059. 1060

In Liverpool - - - - - -	£115,115
In Manchester - - - - - -	60,000
In Glasgow, present - - - - -	59,260
,, ultimate - - - - -	33,645
In London, from Wales - - - - -	95,454
,, from lakes - - - - -	88,000

Formidable objections have been raised to these estimates, as will be seen in the evidence. 6703–36.

51. *Financial Scheme.*—Messrs. Hemans and Hassard agree with Mr. Bateman that the water consumers should be the proprietors of the new works; that a compulsory rate should be levied for water supply on all property within the area benefited; and that the existing waterworks should be purchased and incorporated with the new project, and the companies secured in their present incomes. App. E. 910–12.

They give in their pamphlet a statement of estimated income and expenditure, and Mr. Hassard gives amended figures in his evidence.

52. *Quality of the Water.*—The topographical and geological character of the gathering ground is generally similar to that of the Welsh hills, but is in some respects more

favourable, inasmuch as the hills are higher and steeper and less covered with vegetation, and the area contains less population and less cultivated land. Some portions of the district are less favourable than others, but they might, if it were necessary, be excluded.

The two maps, marked Appendices AZ, 1 and 2, have been prepared to show the geological features of the ground, and its elevation at various points above the mean sea level.

There are extensive lead workings in some parts of the district, but the evidence shows that they need not form any objection to the scheme.

We have made an independent investigation of the quality of the water from this district, in the same manner as that from North Wales; the samples were, as in the former case, collected by Mr. Pole and analysed by Drs. Frankland and Odling, and the reports of these gentlemen will be found in Appendices A and D.

The results of the analyses are very similar to those of the Welsh waters as regards softness and purity, and freedom from mineral contents and organic contamination. But the waters are open to the objection mentioned in the former case as regards the probability of their being coloured by peat. The samples generally were taken in fine weather, but many of these were slightly coloured, and two samples that were taken when the streams were in flood were reported to be "yellowish brown, leaving a nearly black residue on evaporation." It is suggested that these waters might be excluded from the collection and used for compensation, but it is probable that they only represent the state that the streams generally would assume in heavy rains, when the water storage would principally take place. The water taken from the lakes was "clear and colourless, leaving a "slightly brown residue on evaporation."

Remarks by the Commission on Messrs. Hemans and Hassard's Plan.

53. This plan has so many points of resemblance to that of Mr. Bateman, that many of the remarks we have made on the Welsh project will be applicable to this also.

The plan is practicable, and has the advantage of the existence of the natural lakes at a high level, but the estimates of cost are more uncertain than in the former case, on account of the less detail in which the promoters have prepared their plans, the greater length of the conduit, (about 90 miles longer than Mr. Bateman's,) and the greater uncertainty as to its exact route and nature.

The quantity of water obtainable is abundant, as the rainfall, whatever may be its exact amount, is admitted on all hands to be very large.

The quality of the water is satisfactory, subject to the same objections that we have mentioned in the Welsh case.

6916–78. 7149–82. There would probably be less formidable opposition to this scheme than to Mr. Bateman's, on account of the less magnitude and importance of the rivers flowing from the district. But the objections from the possible stoppage of the flow in the conduit would be increased in proportion to its greater length.

The remark we have made as to the necessity for pumping to some extent in the Welsh scheme applies with much greater force to this plan, as the promoters propose to deliver the water into the store reservoirs near London at a level 37½ feet lower than Mr. Bateman. This level we believe would be insufficient to supply any but the lower districts, so that pumping would be required over a large portion of the metropolitan area.

There is no doubt that the lake district is a very fine gathering ground for soft water; but it is deserving of consideration that this district is not unlikely to be claimed as the most natural source of supply for large and increasing manufacturing populations in the north of England, for whom soft water would be particularly valuable; and we hold it to be erroneous in principle that any one town or district should take possession of a gathering ground geographically belonging to another, unless it can be clearly shown that circumstances render such a step justifiable.

MR. HAMILTON FULTON'S PLAN.

3446–3571. 4078–4171. 54. The plan proposed by Mr. Fulton is explained in his evidence, and in the two plans in the Appendix marked A A (1 and 2).

He proposes to take water from the upper sources of the River Wye in Mid-Wales. The reasons alleged for the selection of this district are—

3450. "That it is very thinly inhabited, the water at present is scarcely used at all, either for manufacturing, domestic, or navigation purposes; the fisheries which exist can be protected from injury; there are no manufacturing towns in the watershed; and the only application of water for mechanical purposes is for flour mills, of which there are very few."

He also adds—

"The reason why I have chosen the Wye district in preference to any other is, that the importance of the navigation of the Wye is very small, and consequently the abstraction of its water would be no injury as far as the navigation is concerned. Indeed from the sea up to Hereford, which is the largest town in the district, and which has a population of between 15,000 and 16,000 inhabitants only, I believe the trade is nearly extinguished on the river, that is to say, it is nearly superseded by the railway; and the only trade by navigation which exists now is by the canal from the Severn, which runs up to Hereford." 3174.

Mr. Fulton has selected four districts on the Wye and its head tributaries: App. AA.

	Square miles.
No. 1 containing - - - -	146
2 „ - - - -	125
3 „ - - - -	102
4 „ - - - -	67
Total area	440

Reasoning by analogy with the lake district he assumes a rainfall of 60 inches per annum, and that the net quantity after deducting for evaporation and absorption will be 30 inches. 3454–67.

Taking then the highest district, No. 1, with which he proposes to commence, this would give a yield of 175,000,000 gallons. From this he deducts 44,000,000 gallons for compensation to the rivers, which leaves a net quantity of 130,000,000 gallons fro m this district alone. The four districts together are estimated to yield a net average daily supply of 393,000,000 gallons. Six reservoirs are proposed in the first district as shown in the map, the lowest of them being near Rhyader and at a height of 590 feet above the sea. 3500.

From this point there would be a conduit to London 180 miles long. It would be laid first along the valley of the Wye, so as to take in the water of the other and lower districts when required, and passing Glasbury and Hay; and thence it would pass near Kington, Ludlow, Tenbury, Bewdley, Stourport, Bromsgrove, Henley-in-Arden, Warwick, Banbury, Tring, and Watford, to a point near Barnet, eight miles from Hyde Park, where it is proposed to construct a service reservoir at 276 feet above mean sea level. The aqueduct would be 15 feet wide and 14 ft. 6 in. deep with a fall of from 6 to 24 inches per mile, and it is estimated to deliver 230,000,000 gallons per day. 3519–25.

Mr. Fulton has made an approximate estimate of the cost of the first portion of the scheme, viz., to bring 130,000,000 gallons, which amounts to 7,000,000*l*. For 100,000,000 gallons more the cost would be 2,000,000*l*. in addition. 3531–46. 4093–4102.

55. We have had no evidence on this scheme, except from the promoter himself. We consider, however, that from its general similarity to Mr. Bateman's plan it might be further investigated, if any scheme of the kind for the supply of the metropolis should be deemed necessary.

MR. REMINGTON'S PLAN.

56. Mr. George Remington proposes to bring water from the hills of Derbyshire, collecting it at a point above Mill Dale on the River Dove, 586 feet above the sea, and bringing it by a conduit 135 miles long to a reservoir on Barnet Hill, 300 feet above Ordnance datum. 4321–4442.

He proposes to appropriate an area of 262 square miles, and the following extract from his evidence will show his estimate of the quantity of water obtainable—

4335. What quantity of water do you propose to supply per day at Barnet Hill?—About 100,000,000 gallons. I have put it down in the paper which I sent in to the Commission as 83,000,000 gallons, or one-sixth of the rainfall on the 262 square miles, but in round numbers I would take it at 100,000,000 gallons per day.

The rainfall has been gauged at Uttoxeter, which is on the Dove, but Uttoxeter is very low, and there the rainfall is about 30 inches, and I have assumed the quantity falling on the high district to be 48 inches. 4337.

He estimates that his scheme would cost 5,000,000*l*.

In the absence of more complete data we cannot regard this scheme further than in the light of a suggestion, and we need not remark on it more particularly, except to say that this in any case could only form an auxiliary source; while from the proximity of a number of important manufacturing towns we consider such a source should be reserved for their supply, for which it seems well fitted.

MR. DALE'S PLAN.

1061 *et seq.* 57. The last plan for obtaining water from mountainous districts is that of Mr. Thomas Dale, engineer to the Corporation Waterworks of Hull. This plan is described in his evidence before us, and in a pamphlet published by him in 1866.

He proposes to take water from the same sources as Messrs. Hemans and Hassard, namely, from the Cumberland and Westmoreland lakes; but instead of bringing it by an aqueduct to London, he contemplates conveying it by pipes to supply various towns in Yorkshire and Lancashire.

The plans, Appendices Q (1) and Q (2), will give an idea of Mr. Dale's project. It will be seen that he would convey water from Ullswater and Haweswater first to Leeds and various towns in Yorkshire, and then, by a continuation of the conduit, to Liverpool and other towns in Lancashire.

The following is a list of these towns, and the quantities which Mr. Dale's scheme proposes to supply:—

	Gallons per day.
Lancaster	2 millions.
Preston	8 „
Wigan	4 „
Dewsbury	3 „
Wakefield	3 „
Liverpool	40 „
Leeds	15 „
Bingley	1 „
Kendal	2 „
Bolton	8 „
Blackburn	6 „
Keighley	2 „
Bradford	10 „
Huddersfield	4 „
Burnley	4 „
Rochdale	4 „
Halifax	4 „
Colne	1 „
Bury	8 „
St. Helen's	2 „
	131 „

We have already stated, in speaking of Messrs. Hemans and Hassard's scheme, that this is a favourable district for affording water supply to manufacturing districts in the north; but we believe Mr. Dale's proposal to take the water across the backbone of England to the Yorkshire towns a mistake, as they can be well supplied from districts nearer to them. It would, we conceive, be more advantageous to confine the supply from the lakes to the towns and districts lying to the west of the main chain of hills, and to carry the water more directly to them.

REMARKS ON GRAVITATION SCHEMES GENERALLY.

58. The experience with plans for supplying large towns with water by gravitation, from catchment reservoirs formed in hilly districts, has not yet been so extensive as to enable engineers to make accurate calculations, in all cases, as to their sufficiency.

App. BB. Liverpool, for example, was originally supplied by pumping from the red sandstone strata under the town; but some years ago, this source proving insufficient, large works were established for bringing water by gravitation from the Rivington Hills. The supply however proved much less than was expected, the sandstone had again to be resorted to, and now additional sources are required. It was anticipated, on good authority, that a supply of 12 or 13 million gallons per day from the new works might be reckoned on; but our evidence says—

> The Rivington Works are practically a failure as gravitation works; three dry years in succession reduce the available water to six millions of gallons per day, and four successive years of drought, which may very probably occur in future, would reduce it still further; and unless enormous reservoirs or lakes could be made, capable of storing the surplus waters of three or four years; these works must prove insufficient.

At Newcastle-on-Tyne gravitation works were constructed in 1848, but in 1850 the supply failed, and the former establishments for pumping from the Tyne had to be again resorted to. Enlargements of the gravitation works were carried out, but still with insufficient results, and a permanent pumping establishment is now in course of erection.

Bristol was supplied in 1851 by gravitation from the Mendip Hills; in 1864 the supply failed, and after enlarging the works, recourse was had to permanent pumping works from springs nearer the town.

59. During the sittings of this Commission the gravitation plans throughout the country have been subjected to a severe test by the occurrence of an unusually long drought in 1868. Although the rainfall of the whole year was above the average, yet it was very unequally distributed, as from the end of April to the end of September, a period of five months, there was scarcely any rain. Hence the capacities of the catchment reservoirs were severely tested, the towns having to depend entirely on the stores in them, without any feeding supply except that of perennial springs.

We have had evidence on this point from Mr. Bateman, Mr. Hawkesley, and Mr. John Taylor, chief assistant to the late Mr. James Simpson, who has given us, in Appendix B C., the result of inquiries made as to the effects of the drought in several towns.

60. In Manchester it appears that after official notices had been published cautioning the inhabitants against waste, and urging them to economize their supplies, the corporation, on the 3rd of August, limited the supply to the city to 12 hours of the day, stopped the street watering, and diminished the trade supplies by one half. They also made an arrangement with the millowners for reducing by one half the quantity given to the mills on the line of the river, and made compensation in money for the deficiency. In the middle of September the general supply to the town was further limited to eight hours per day, and the quantity for trades also diminished. Many persons were prosecuted for waste or undue use of water. The eight hours' supply lasted seven days, and the 12 hours' supply 76 days.

The following are extracts from Mr. Bateman's evidence in regard to this case:—

With regard to the quantity of water supplied to Manchester during the drought of 1868, you stated that the balance left in store on the 25th of September, after 150 days drought, was 435,000,000 gallons, but that during 45 days there was a diminished quantity supplied to the mills, and further that during 52 days the water was shut off at night. Supposing the supplies to the mills and to the town to have been continued to their full amount during this period, have you calculated what would have been the quantity in store?—We should have exhausted our store, and we should have been, perhaps, something like 200,000,000 or 300,000,000 gallons deficient. 7427.

You are preparing larger storage, are you not?—Yes. Our works are now very far from being complete, but we are constructing two new large reservoirs; and we have a third reservoir which we have never been able to fill owing to the bad foundation, which, as soon as the two others are completed, we shall restore, and that will nearly double our storage at once. It is a mere question of storage in Manchester. We have abundance of water, but we are two years behindhand in our works, and we are two years beforehand in the calculated supply. We have been extending the supplies to the outlying districts so much that, while we have been falling behind in our engineering operations, we have been going too fast in the supply of water to the district, and therefore the two causes together put us into this position this year. 7428.

In our Manchester Waterworks we are at present incomplete. We are behindhand in several of our reservoirs which we are now constructing, and we are beforehand with the quantity of water which we are supplying, so that we are not quite equal to what we should be in storage, and therefore we were not able to give the full supply of water which we could have desired during the last drought. Our available storage in Manchester is equal at present to only 24,000 cubic feet of water per acre of collecting ground. In Liverpool the storage is equal to 48,500; in Dublin it is equal to 25,500; at Loch Katrine it is equal to 30,000; and at Gorbals it is equal to 52,000.

At Rochdale, as early as the 25th June, the supply was limited to four hours per day for 15 weeks; but with this precaution, during the second week in October the store became entirely exhausted, and the town would have been almost without water but that recourse was had to pumping from a colliery in the neighbourhood.

At Bury the store ran so low towards the end of August that it was reserved entirely for compensation to the mills, and the company obtained a supply of seven gallons per head from neighbouring works; for baths and for the numerous manufacturing and trade uses in the town there was none. This continued for five weeks.

At Preston the reservoir became practically dry at the end of August, and costly pumping works were hastily established, which were required for 58 days.

At Kendal the reservoirs were exhausted earlier, and measures of the same kind were adopted.

At Newcastle the gravitation works would have failed for many weeks had they not been supplemented by the pumping from the Tyne.

At Bradford 60,000 of the inhabitants were limited to one day's supply per week for 16 weeks, and 90,000 had their supply gradually reduced during five or six weeks to six hours per day. The want of water for manufactures was here seriously felt.

At Halifax the reduction began on the 11th of May; the domestic supply was limited to 14 hours per day for 66 days, to 10 hours for 10 days, and to six hours per day for 86 days; the supply to large consumers being gradually reduced from 30,000 to 1,000 gallons per day.

At Sheffield the supplies were first reduced in June, and further in July, August, and September, the last reduction being to four hours per day.

The towns of Stockport, Bolton, Ashton, Stalybridge, Oldham, Dewsbury, Warrington, Blackburn, and others suffered more or less, and Mr. Taylor concludes his report with the following remark:—

> The general result has been that nearly all gravitation supplies of water, obtained from drainage grounds, have failed in a manner hitherto unprecedented within the known experience of such works, proving that the data on which they have been based have been fallacious, and that the storage reservoirs and gathering grounds of such works must be greatly increased to meet the demands of years like the present.

61. The causes of this difficulty may lie either in an over-estimate of the available rainfall or in an insufficient provision of storage. The sufficiency of water-collecting plans in these respects must be tested both by the concurrence of several consecutive dry years and by occasional droughts of long duration; and to obtain the necessary data on these points, for any particular district, must require special observations on that district extended over a considerable time.

62. In so variable a climate, and with a rainfall in different parts of the kingdom ranging in round numbers from 20 to 100 inches, it is of primary importance to have the most complete information as to the rainfall, and, as the annual variation is also great, the average fall for a term of years cannot be determined without observations extended over a long period. Less than 20 years would probably not suffice. But the question, with reference to a water supply, has to deal not with the average rainfall of a long term of years, but with a short term depending on the capacity of the storage. In no case yet contemplated would it be prudent to rely on more than the average of three years, and under certain conditions it is doubtful whether two years would not be a safer term.

The Rev. W. Jenyns, in his "Observations on Meteorology," gives an instance in which, even with a term of 10 years, the average varied 7½ inches, the mean quantity in one case being 18½ and in the other 26 inches. In two other terms of 10 years the difference was 2·331 inches.

The experience, however, of half a century would seem necessary to determine the minimum fall for a short term of years. We may take the annual rainfall recorded at the Greenwich Observatory from 1815 to 1868, to average 24 inches. From these observations it appears that during this period of 54 years there were three years in which the rainfall was under 17 inches, or only about two-thirds of the average, viz., in 1832, 1840, and 1864; that during the same period there was one term, and one term only, of three years, 1832–4, in which the average amount of rainfall was a quarter short of the average annual fall; that there were four terms of that length in which the annual rainfall was from a quarter to a sixth short; while once in the 54 years there was a term of five years, the rainfall of which averaged nearly a sixth short. These variations are shown in the following table:

Length of Term.		Average annual Rainfall.	Quantity short of general Average of 24 Inches.
		Inches.	
1 year	1832 (doubtful)	16·1	−7·9
	1840	16·6	−7·4
	1864	16·4	−7·6
2 years	1832–3	18·5	−5·5
	1834–5	20·2	−3·8
	1857–8	19·6	−4·4
	1863–4	18·05	−5·95
3 years	1832–4	18·3	−5·2
	1856–8	20·4	−3·5
5 years	1854–8	20·8	−3·2

The short three-years terms occurred at intervals of 22 years; for the short five years the limits of recurrence are not yet reached.

In the mountainous districts of England the irregularity of the rainfall is still greater. Mr. Symons has given evidence showing that in a period of 22 years at Windermere it has reached as high as 116·26, and fallen as low as 47·54 (1861 and 1855), whilst once in that time the mean of three years (1855–57) did not exceed 52·71. The mean of the 22 years was 79·85.

It is evident, therefore, that a very long series of observations is necessary to be made before any authoritative opinion can be expressed, not only as what may be the true average annual rainfall, but what (for this inquiry is still more important) may be the mean of the three driest years, and at what interval they may occur. In the case of a large city like London, when such a source of supply is proposed, an exact determination seems to us imperative. Of course it will be understood that not only should the observations extend over a long term of years, but also that they should be made in many places so as to get at the average rainfall of the district, which Mr. Symons has well shown to have very different values in immediately adjacent places; as it varied in the same year in fourteen areas in the Lake district, from 45 to 100 inches. When the rainfall has been determined with exactness, the proportion which can be delivered in a hard rock district may be estimated with considerable accuracy.

The system of collecting grounds utilizes, no doubt, the rainfall to the greatest extent. But the great disadvantage is, that the springs to fall back upon in time of drought are insignificant in comparison with the great quantities stored in permeable strata; the very circumstance of a large immediate delivery of the rainfall precludes the possibility of that subterranean storage of a large portion of it, which forms so valuable a resource during severe and long-continued droughts.

63. The question of storage room involves complicated considerations, which have been especially dwelt upon by Mr. Hawkesley. On account of the irregularity of the rainfall, particularly in mountainous districts, it is impracticable to construct reservoirs large enough to store the entire quantity received, so that all large floods occurring when the reservoirs are full must pass away and be lost. Hence the available average obtainable from reservoirs must fall much short of that deduced simply from the fall of rain. We cannot here enter further into this question; but the experience we have above mentioned suffices to show the difficulty of making reliable calculations on this head, even when tolerably complete data are at hand.

64. It is worthy of remark that during the exceptionally long drought of 1868 the Thames and the Lee seem not to have been diminished in volume below the ordinary flow of dry years, a result entirely due to the equalizing effect of the great subterranean stores contributing to their flow.

We shall hereafter go more fully into the advantages of these rivers as sources of supply, which cause them to contrast so favourably with gravitation schemes.

PART II.

ON SOURCES OF SUPPLY OTHER THAN THE MOUNTAINOUS DISTRICTS OF ENGLAND AND WALES.

65. Your Majesty's Second Commission commanded us to inquire "whether there are "other districts, in addition to the high districts of England and Wales, from which a good "supply of unpolluted and wholesome water can be obtained."

Several plans or proposals, of various degrees of magnitude, having for their object to supply the metropolis, wholly or partially, from sources of this character, have been mentioned to us by the parties named in the following list. It will be convenient to divide these into classes, as follows:—

Class I.

From the River Thames or its Tributary Streams.

1. Mr. McClean, from the Thames near Henley.
2. Mr. Bailey Denton, from the higher parts of the Thames basin.
3. Mr. Brown, from the same.
4. Mr. Bravender, from the same.

Class II.

From the Lee.

5. Mr. Mylne, from the upper part of the Lee basin.

Class III.

From the Chalk and Oolite Formations in the Basin of the Thames.

6. The Rev. J. C. Clutterbuck, from the chalk and oolitic area of the Thames basin.
7. Mr. Homersham, from wells in the chalk around London.
8. Mr. P. W. Barlow, from certain chalk springs in North Kent.
9. Mr. Meeson, from chalk springs at Grays in Essex.

Class IV.

Miscellaneous.

10. Mr. Thos. Hennell, from the chalk and Bagshot sands of the neighbourhood of Basingstoke and Farnham.
11. Mr. G. W. Ewens, from certain chalk springs near Havant.
12. Mr. Telford McNeil, from the Bagshot Heath district.

A plan proposed by Mr. A. S. Ormsby, to collect water from artificial drainage surfaces, does not appear to come within the scope of our inquiry.

Some of these projects are merely suggestions, and none of them have been prepared with the completeness and detail of the larger plans. It will, therefore, not be necessary to notice them at the same length.

CLASS I.

From the River Thames or its Tributary Streams.

66. Several projectors, considering that the Thames when it reaches Hampton has become polluted by the drainage of the land and towns above, have proposed to take the water at higher points, generally combining with their propositions other suggested arrangements for the improvement of the supply.

Mr. McClean's Plan.

5498 et seq. 67. Mr. McClean, M.P., Civil Engineer, gives a description of a plan which he brought forward in 1849 and 1850, in conjunction with the late Mr. Blackwell, who was for many years engineer of the Kennet and Avon Canal. It is illustrated by a plan and section which are printed in Appendices T (1) and T (2) to our report.

Mr. McClean's proposition is to embank and canalize the Thames above Medmenham (between Henley and Great Marlow), so as to form, in the present channel of the river, a long series of impounding reservoirs, which would be advantageous not only for storing water but also for improving the navigation. He would then take the water from the lowest of these pounds, 105 feet above low water in London, and proposes thus to obtain a supply of 200,000,000 gallons a day.

The drainage area included is 2,500 square miles, and the mean annual rainfall is estimated at 26 inches.

The aqueduct would be a canal 36 miles in length, the last five miles to be covered. It would be 40 feet wide by 12 feet deep, and is intended to deliver the water in London at about the level of the Paddington Canal, or the New River head, from which level Mr. McClean assumes all the low part of London might be supplied by gravitation, that necessary for the higher parts being pumped to elevated reservoirs at Hampstead and Clapham.

Mr. McClean believes that the quality of the water taken at Medmenham would be very satisfactory.

The estimate for the plan when brought forward was 1,500,000*l.*, excluding the pumping parts of the scheme.

Mr. McClean gives further details, and says he has no doubt that by storing the flood waters in the upper reaches of the Thames more water may be obtained than can ever be required; and that by embanking the river in the way he proposes he would increase the quantity by preventing the water going out on the lands and inundating them, whereby a great deal is lost and the quality much deteriorated. 5637. 5718–21.

Mr. Bailey Denton's Plan.

68. Mr. Bailey Denton's plan, which is illustrated by a map, Appendix V., is thus generally described by him :—

"I am prepared to show that the upper streams of the Thames basin, the tributaries of the Thames, are capable of supplying the metropolis if supplemented by storage, and that that storage would partly consist of the water of under-drainage and the water of drainage by arterial improvements from the upper lands which form the margin of the Thames basin. I should state, however, that my proposal is to take from the Thames and its tributaries, at points above which water may be obtained in positive purity by the proper exercise of conservancy, all that may be required for the supply of London, having stored in winter the surplus waters of that period of the year in order to repay the river system in summer what may be required to maintain it at a fixed standard height." 1532.

With respect to the quantity of water available he makes the following remarks :

"To give some proof that there is water sufficient, I would just mention these facts to the Commission. The area of the watershed of the Thames is 3,300,000 acres, the population we may take at 4,500,000, the average rainfall is 26 inches, the minimum is between 19 and 20 inches, and that minimum is disposed of in this way—3 inches support the perennial supply of the river, that is to say, maintain the river in summer at the ordinary height; taking 3 inches from 20 there remains 17, and of that 17 we find by information of various sorts that a very large share runs off to the sea in winter; but, beyond the fact that this accretion occurs when the rivers are full, there is another fact, that whatever water is taken by under-drainage from the atmosphere it is so much positive increase to the river supply, and as under-drainage proceeds so will the supply be increased." 1547

"I propose to collect the water from the higher portions of the basin, that is, from the oolitic sources on the north of the Thames, say from Cricklade to Oxford, and from the various streams rising in the chalk throughout the whole of the area of 3,300,000 acres. It is not possible to state the quantity of water discharged by springs from the water-bearing strata of the Thames basin, but it is pretty accurately known that, while 1½ inches of rain maintains the ordinary summer flow in the river from April to September inclusive, at least 4 inches runs off during the remaining six months from October to March inclusive, without taking into consideration excessive floods. The ordinary winter flow, in fact, compared with the ordinary summer flow is as 2½ to 1. No dogmas as to loss by evaporation and other causes touch this fact, which manifestly proves, when the discharge drainage water is taken into account, the capability of storing in winter all that can possibly be required for compensation in summer." 1557.

"My proposal embraces three sources of supply with a means of future augmentation, viz., the upper sources of the Thames giving 100,000,000 daily, the Lee giving 60,000,000, the Wey and the Mole giving 40,000,000, making 200,000,000 daily, exclusive of the Colne and the Wandle, which with storage may provide a share at some future time." 1651.

"I have already observed that there is almost a total absence of any reliable gauging of the Thames and its tributaries, but we do know this from the evidence of Mr. Stacey before the Rivers Commission, and a remarkable fact it is, that the general summer average volume at Wolvercot, which is just above Oxford, is 73,000,000 gallons *per diem;* but in the dry summer, 1865, it was reduced to 62,000,000 gallons. But the winter flow is represented by very different figures. On the 2nd of January 1863 the quantity flowing down was 321,000,000 gallons, which is represented as the ordinary winter flow; it increased gradually in five days to 350,000,000, 430,000,000, 588,000,000, 636,000,000, 702,000,000, and 742,000,000, which was the highest it arrived at. I submit that that must go some way to prove the capacity of the Thames basin to supply water if the surplus be stored in winter, to compensate the rivers for what may be taken out of them in summer. It will be observed that Mr. Stacey represents the ordinary winter flow at Wolvercot as about 4½ the ordinary summer flow, instead of 2½ times as I prefer to take it." 1662.

At Lechlade the Thames and Severn Canal joins the Thames, and higher up the North Wiltshire Canal joins the Thames and Severn Canal. Mr. Denton proposes to purchase those canals and utilize them for the collection of the waters of the Thames above, and then to bring the water from Lechlade to London by a conduit, 127 miles in length. This conduit would collect the waters from the various tributaries, the Coln, the Leash, the Windrush, the Evenlode, the Cherwell, and the Ray, into a concentrating reservoir just below Oxford; then, passing down from Oxford to London, the Ock would be in the same way brought under contribution, as well as the Thame, the Loddon, and the Hertfordshire Coln. The main conduit would start from Lechlade at a height of about 220 feet above ordnance datum, and would bring the water to Hampton, where Mr. Denton proposes to deliver it to the present water companies, for them to raise to high-service reservoirs for distribution by gravitation.

He proposes to have compensating reservoirs on the impervious bed of the Oxford clay.

The Wey and the Mole would have a separate system, and be added, when the demand increased. The water from the upper portions of each stream would be brought down by a channel above the surface of the ground of the main valley, so that no flood water or polluted water could enter.

1603. He proposes to intercept the sewage in two ways; for a certain distance up each contributing stream it would be by open drains, but above that (and in fact wherever it would be more economical), there should be compulsory power to raise and apply it to the hills, so as to favour a complete absorption of the sewage into the soil. Mr. Denton says—

1620. "Such a plan must be preferable to irrigation on low meadow ground, where the effluent water, passing *over* instead of *through* soil, must always be charged with a certain proportion of sewage in solution, if not also in suspension. A study of the geological character of the upper portions of the Thames basin—the chalk and the oolite—will satisfy you that, maintaining as they do the river system of the Thames, they are capable of absorbing sewage to any amount, with benefit rather than injury to the springs themselves."

The cost of the works is estimated by Mr. Denton at about 5,320,000*l.*

He does not propose that the cost of the interception of the sewage should form any part of his scheme, as in two years the towns will be bound to carry it out themselves.

6838 et seq. 69. *Mr. T. C. Brown* of Cirencester has given valuable data as to the rainfall in the upper part of the basin of the Thames, from 1845 to 1868; it varied from 19·9 inches in 1854 to 48·8 inches in 1852, and the mean of the 23 years gave 30 inches. He gives information as to the sources of water in the Upper Thames district, and suggests that London might be supplied with pure water, for drinking purposes only, to the extent of say six to nine millions of gallons per day from these sources, conveying it to London by pipes along the Great Western Railway.

App. H. 6888 et seq. 70. *Mr. Bravender*, land agent and surveyor at Cirencester, who has also devoted careful attention for a long period to the upper part of the basin of the Thames, gives important geological and hydrological information on the subject, which will be found in his evidence and in Appendix H.

Regarding the springs in the oolites, we may make the following extracts:—

6906. What is the sum total of those various springs which you have described; you have described Boxwell spring which gives a yield of above 1,000,000 gallons a day, and you say that the pump at the Thames head delivers 3,000,000 gallons a day; can you enumerate the other springs?—There is a spring at Ewen which gives the same as Boxwell spring, or a little more than 1,000,000 gallons. There is Ampney spring at Ampney Crucis, two miles east of Cirencester, which is thrown out from the fuller's earth by a fault, and which gives out an enormous quantity. I find in April /66 I measured the entire flow near the mill and found it to be considerably more than 20,000,000 gallons in the day; and yesterday I visited this spring and carefully measured the flow of water, and find that upwards of 30,000,000 gallons were passing the bridge near the mill. I also visited Bibury spring and found it discharging rather more than the one at Ampney Crucis. There is a spring about a mile above that at Ablington which I have also gauged, and that gives out quite enough to turn a mill; the discharge is more than 2,000,000 gallons. Then there is a spring above Winson from the same source which gives out about a million and a half. The Bibury, Ablington, and Winson springs are on the Coln, the Ampney spring is between the Churn and the Coln, the Ewen spring falls into the Thames at Ashton Keynes and does not get into the Churn.

6907. What are the limits of height above the sea within which those springs occur?—They are all about the same level as Cirencester, or a little higher, from 300 to 380 feet above the sea.

He proposes to add about one-third to the present supply of the water companies, by collecting water in the valleys of the Churn, the Coln (Gloucestershire), the Windrush, and the Ock, and conveying it by a conduit or pipes to London.

Mr. Bravender estimates that about 9 to 11 inches of the mean annual rainfall is available over the whole district.

CLASS II.

From the Lee.

71. The possibility of increasing the supply from the basin of the River Lee, by storage reservoirs or otherwise, has been alluded to by several witnesses, but the only definite plan laid before us for this purpose is the following:—

Mr. Mylne's Plan.

72. Mr. R. W. Mylne, son and formerly assistant of the late Mr. Mylne, who was for 50 years engineer of the New River, has proposed a plan for increasing the supply of water from the basin of the River Lee, which is described at great length in his evidence, and is illustrated by the map, Appendix Z. 4972 et seq.

He proposes to make the drainage area better available by collecting the streams and chalk springs into impounding reservoirs to be formed at various places, but principally at Enfield Chase, which, being on the London clay, is, he conceives, more favourable for the purpose than any sites that can be found on the Lee proper.

This plan would, he states, bring 70,000,000 gallons daily into London, in substitution for the present supplies of the New River and East London companies, adding therefore about 28,000,000 gallons. This would be, he says, a minimum on the driest years.

The cost of these works, excluding compensation, is estimated by Mr. Mylne at 1,250,000*l.*

The following extracts from Mr. Mylne's evidence will illustrate the nature of his plan:—

"In contradistinction to the view recently put forward, that no means of storage could profitably be carried out without descending as low in the valley as Broxbourn or Waltham, it is herein suggested that a considerable quantity from the upper tributaries mostly of pure spring water might be diverted and transferred by gravitation from a point above Hertford direct to convenient sites for reservoirs at Enfield Chase on the London clay beyond and altogether outside of the watershed of the upper portion of the Lee basin, and a further quantity might be impounded within the basin in the valley of the Rib. It is proposed to make diversion cuts on the before-named four tributaries, viz., the Lee proper, the Mimram, the Beane, and the Rib, and convey the collected quantities along an artificial channel to a point in the valley 2½ miles above Hertford; the total contributing area would be 246 square miles, giving an average daily yield of 43,000,000 gallons, but it is only proposed to take 40,000,000 gallons, and to convey that volume in a direct line to London through a tunnel and covered channel 5½ miles in length into reservoirs proposed to be made on Enfield Chase. The two proposed reservoirs to be made, into which the waters would gravitate, will cover an area of 270 acres, and will contain, including the tunnel, 1,391,000,000 gallons with a top-water level of 130 feet above Trinity high-water mark and a maximum depth of 37 feet of water. . . . . In order to increase the extent of reservoirs on Enfield Chase, and to bring a higher water level into use for distribution, it is proposed to construct four further reservoirs at the additional height of 36 feet, and to lift into them by steam power a considerable portion of the collectable quantity entering into the two gravitation reservoirs previously described. These will cover an area of 340 acres and will contain 1,249,000,000 gallons, with a top-water level of 166 feet and a maximum depth of about 38 feet of water. The total storage capacity of the six reservoirs on Enfield Chase would therefore amount to 2,640,000,000 gallons or 423,552,000 cubic feet. The execution of the tunnelled part would be throughout its length entirely in chalk and being near to the upper surface of the chalk and overlaid with tertiary sands and intersecting the local disturbance already alluded to, as well as across the general dip of the chalk, no doubt a considerable quantity of water may be expected. It is assumed that from the tunnel works, with the additional seven square miles of gathering ground at its southern end, together with the Lee tributaries, it will secure a total daily yield of at least 47,000,000 gallons. The storage capacity necessary for securing a uniform daily flow has been ascertained at Feilde's weir to be for 118 days 66,000,000 gallons a day, and inasmuch as the volume is proportionably much larger and more constant from the upper tributaries, it is estimated that a provision of 90 days' storage would be quite sufficient for the intended gathering ground. On the Rib it is proposed to adopt the plans designed by the late Mr. Rendel for the reservoir below Standon, which exceeds 200 acres, and would hold above 500,000,000 gallons, with a maximum depth of 20 feet of water. . . . . Besides the works contemplated for the diversion of the upper tributaries of the Lee, it is intended to retain the New River channel for the flow of the Chadwell spring, and to collect all the springs issuing from the west bank of the valley between Amwell and Rye House, and lift them by steam power about 10 to 15 feet into the New River; also to purchase the water rights of the copious springs which now work Hoddesdon Mill and to collect those and others in the locality, and lift them also from 15 to 20 feet into the New River. Those sources, it has already been stated, may be calculated upon to yield the respective quantities of 4,500,000, 6,000,000 and 8,000,000 gallons per day, and out of the gravels and sands near Hoddesdon, where the water is assumed to absorb and soak away into the sands under the London clay, a quantity of at least 4,500,000 may be estimated, and could be lifted into the New River at a height of not more than 20 feet. A very much larger quantity from this source might possibly be obtained, but perhaps only effectively by longitudinal adits or driftways up the sides of the valley, works which are not contemplated in the present scheme. The collective quantity of all these strictly spring waters could be secured at a very small cost, and would amount in quantity in dry seasons to about 23,000,000 gallons per 4995

day, a volume equal to the present flow in the New River, and therefore, notwithstanding the proposed abandonment of all further abstraction of water out of the Lee at Ware, the New River would remain in its present condition as to volume as far down as Enfield, where further works are suggested. . . . . With regard to the manner of distributing the total daily yield of 47,000,000 from the store reservoirs and 23,000,000 gallons from the New River, in all 70,000,000, there are various modes of division that might be made, but considering that two companies have to be provided for, it is suggested that the East London Company should have 30,000,000 delivered over 24 hours, from filter-beds placed at the foot of the high-level reservoirs, and pipes from thence to Stamford Hill, delivering at the level of 112 feet into a service reservoir. The East London Company have a small reservoir at Stamford Hill, and I propose by means of a large main to deliver there at the level of 112 feet, and from thence the distribution over the whole of the East London district would be by gravitation, except perhaps a small area immediately in the vicinity of Stamford Hill itself."

5000. "The advantages to the East London Company are, that the water would be drawn from a purer source than at their present intake, being freed from the valley drainage and future cost of diverting it, and obtaining a gravitation supply in lieu of pumping, and the New River Company would have an increase and improved supply, freeing them from the necessity for many years to come of looking to the river Thames or other distant sources, but confining their endeavours to within the legitimate and as yet unutilized valley waters of the river Lee."

5024. "That would be 63 days' storage on Enfield Chase, with a further storage on the river Rib."

CLASS III.

From the Chalk Formations in the Basin of the Thames.

73. Many witnesses have alluded to the great natural storage of water in the porous strata, chiefly the chalk, which form so large a portion of the drainage area of the Thames basin. By reference to the geological map (Appendix Y.), and to the evidence of

3041. Mr. J. T. Harrison, it will be seen that out of 3,676 square miles of surface no less than 1,047, or two-sevenths of the whole, consist of the chalk downs so well known, and extending so widely over this part of England. These strata absorb and store a large portion of the rainfall; and although much of this store finds its way by springs into the streams, and so already contributes to the supplies drawn from them, there has always been a desire on the part of those interested in water collection to go in preference directly to the stores themselves.

The water in the chalk round London has repeatedly been proposed as a source of supply, either wholly or partially, for the metropolis. The New River was constructed to take advantage of chalk springs, and a large portion of the water it at present conveys comes from this source.

It is on record that in 1827, Martin, the artist, proposed to bring the water of the Colne (the principal chalk river to the north of London) to the metropolis, and Mr. Telford, in 1834, proposed to supply London from the Verulam and the Wandle, both effluents directly from the chalk. A few years later, in 1840, a company was started called the London and Westminster Water Company, who chose Watford as their source, backed by a strong approving report from the late Robert Stephenson; and some years later this was revived under the name of the London (Watford) Spring Water Company.

The Chemical Commission of 1851 devoted considerable attention to the examination of the chalk water, and recommended it strongly as the best supply for the metropolis, on the ground that the quantity was large, and the quality superior to that of any other water that could be obtained. The following extracts from their Report will illustrate their views on the subject:—

"The water which it is proposed to bring from the neighbourhood of Watford, for the supply of the metropolis, claims consideration as being entirely spring water, and has a peculiar scientific interest as representing the pure primitive basis of the river water which is at present consumed. A supply of water of the same description is also offered from the south side of the river, to be derived from the chalk strata upon the line of the South-eastern Railway, and the quantity attainable on either side is said to be so considerable as to exceed the actual requirements of the metropolis. Of the chalk district, which surrounds London on all sides, and covers an area of not less than 3,000 square miles, the upper strata appear to be charged with water to a height of several hundred feet above the level of the sea. This water issues again in numerous natural springs, or may be reached by moderate boring. The daily yield of single springs or of artificial wells in some parts of this district is remarkable for its quantity, often amounting to 300,000 gallons, and occasionally rising to 1,000,000 gallons and upwards; a copiousness of flow, which is referred to the chalk rock being highly pervious to water, from its fractured and cavernous state. This chalk spring water is not to be confounded with the water of the deep wells of London, although the latter are carried into the chalk strata below the clay, but differs as completely in composition from the latter as any two waters can well do. Nor does any evidence exist of a relation or dependence of the London deep wells upon the water of the chalk districts; nor reason to infer that the yield of the latter would be restricted within the narrow limits of the former. Indeed, all grounds for comparison of the two waters will disappear if it is true, as many well-informed persons believe, that the

deep wells of London draw their supplies chiefly from the sands under the blue clay and above the chalk, the water of which sands appears to flood the upper beds of the chalk. The superposition of the thick mass of strata which form the London clay, certainly alters considerably the condition of the chalk below it, and renders it no longer comparable with the water-bearing strata of chalk in Hertfordshire and Kent, which are not so covered, and are situated above the level of the sea. The whole original supply of the New River Company, from the Chadwell and Amwell springs, was water of the kind under consideration, and a very sensible proportion of the present large supply of that company is still spring or well water of the same nature."

"On comparing the Watford spring water with the New River water and Thames water as supplied by the water companies, a considerable similarity is observed in the character of their saline constituents. The lime is in larger quantity in the spring water, but then it is nearly if not entirely in the state of carbonate. The earthy sulphates, which give rise to permanent hardness, are almost entirely absent from the spring water. The general character of this supply may be further described as follows:—

"1. The spring water contains no matter in suspension to cause turbidity or colour; its clearness and brilliancy are unexceptionable.

"2. It possesses a desirable coolness, having at all seasons a temperature between 50° and 52°.

"3. The amount of organic matter it contains is inconsiderable, and of a kind which appears to be incapable of undergoing putrefactive decomposition, so that it may be safely disregarded.

"4. The salts which it contains would not interfere with its use as a beverage. It is indeed a choice water for drinking."

We have received the four following propositions for utilizing this source.

74. The *Rev. J. C. Clutterbuck*, who has paid much attention to this subject, gives his views upon it at considerable length. 1782 et seq.

He believes that considering the large chalk springs issuing at high levels in various places round London, it would be possible to find in such springs a considerable quantity of water, of good quality. The most reliable sources are springs in the chalk, and speaking of their abundance he says:—

"Along all valleys in which rivers run, the Kennet, for instance, the chalk streams are fed from their sources down to the place where they deliver themselves into the river, because they run just on the springs, and are fed as they go. You may not see very large springs, but you will see an immense gathering of water in the course of the river by the discharge of the water from the springs." 1836.

He disapproves, however, of obtaining the water from the chalk by pumping, in regard to which he says:—

"You would obtain a certain quantity, but it would be at the expense of the rivers; the rivers would cease to flow. When my advice has been asked I have invariably said, Take the water as it flows above ground, and do not tamper with it below; that is what I have invariably said, and I believe it is sound advice." 1837.

By taking the water as it flows down the rivers, and by an arrangement of reservoirs, he considers there might be an immense storage of water in the upper districts.

The springs in the chalk under London have, he considers, been over-taxed, and the consequence has been an unnatural depression of the water. Any hope of obtaining a supply for the metropolis from this source would in his opinion be a failure.

75. *Mr. Homersham*, civil engineer, who has supplied Caterham and other districts with water drawn from the chalk areas round London, proposes to supply the metropolis entirely with spring water from the chalk, and to do away with the present supply taken from the Thames. He believes that there would be no difficulty in getting from this source a very large quantity. The cost would be small, by reason of the readiness and cheapness with which water can be obtained from the chalk in well-selected situations. He considers that any objection to the hardness of chalk water may be obviated by the use of Dr. Clark's softening process, in which he has had considerable experience. 6762 et seq.

The water at Caterham appears by Dr. Frankland's analysis to be remarkably free from organic matter. App. AX (2.)

76. *Mr. P. W. Barlow*, civil engineer, believes that the ultimate solution of the difficulty of supplying London will be found in the chalk. He has found several powerful springs issuing from the chalk on the south side of the Thames; in one small district near Gravesend they amount to 10,000,000 gallons per day. He believes that by driving a tunnel parallel with the river, 20 miles long, from Lewisham to Gravesend, or a little beyond, 60,000,000 gallons per day might be obtained. 5959 et seq.

77. *Mr. R. Meeson* has given us an account of large springs issuing from the chalk pits at Grays, in Essex, and which furnish an abundant supply. The water is of good quality, limpid and of uniform temperature, very similar to that of the Amwell springs, but rather harder, being 16·6° of Clark's test. About 450,000 gallons per day are at present used to supply Brentwood and Romford and parts adjacent. About 6863 et seq.

7,000,000 gallons per day have, however, been raised, and Mr. Meeson believes the springs would supply 10,000,000 at least.

We add some extracts from Mr. Meeson's evidence:—

"The water springs are situate in the chalk pits at Grays in Essex, about a mile distant from the Thames. When undisturbed they rise to a height varying from about four feet to eight feet below Trinity high-water mark. . . . . The depth of water which passed over the gauge, which was 3 feet 8 inches wide there, was $5\frac{1}{4}$ inches, so that the quantity then obtained every 24 hours exceeded 2,100,000 gallons, besides that used on the works. This quantity was delivered daily, the engines being worked day and night, ceasing for only a few hours between Saturday evening and Sunday morning. During the week the water was lowered about 12 feet, and it then became possible to excavate the chalk to that additional depth over a small space; but when the engines ceased working the water speedily rose to its former height, and it occupied an entire day and night so to reduce the water as that work might be resumed; and throughout the entire remainder of the week the springs yielded the supply I have mentioned, which was all that the pumps then in use were capable of delivering. . . . . These operations have been carried on now for many years, yet notwithstanding so large a quantity has been pumped daily into the Thames, no perceptible alteration has taken place in either the quantity or quality of the water."

CLASS IV.

Miscellaneous Schemes.

Mr. Hennell's Plan.

1913 et seq. 78. Mr. Thomas Hennell proposes to bring 14,000,000 gallons of water per day to London, in extension of the present supply, from the Basingstoke Canal, and from sources adjacent to it, aided by storage reservoirs to hold 840 millions of gallons. He would purchase the canal from the company and use it as a conduit, forming a paved brick channel throughout its length.

He calculates that six-sevenths of the water would come from the chalk at the Basingstoke end of the canal, where it is 252 feet above ordnance datum, and the remainder from the district of the Bagshot sands between Farnborough and Woking. The quantity might, however, be largely increased.

In answer to questions respecting the springs intersected by the canal in passing through the chalk below Basingstoke, Mr. Hennell states:

2013. "To take first the Whitewater; that I found in October contained, in round numbers, 10,500,000 gallons. I propose to take one-third of that, and that is rather the largest of the three principal sources."

2014. "I measured the stream again last week, and I found 14,500,000 gallons daily. Then, in addition to that, there are the Mapledurwell and the Newram springs within a mile of Basingstoke."

2015. "The Mapledurwell springs contain 1,980,000 gallons. There are springs east and west of the village; those which are on the east side of the village I cannot conveniently take, because they are at a low level, but they unite afterwards, and therefore I take two-thirds of the western springs only, which would be equal to one-third of the whole. They unite before they come into any stream where they would be required, and therefore I take two-thirds of 1,980,000, that is 1,320,000. Then the Newram springs contain, in round numbers, 4,500,000, of which I take two-thirds; that is 3,000,000."

2016. "The entire total is 28,296,000."

The water would be conveyed by the canal to a point near Weybridge, from whence a conduit eight miles long would have to be made to Thames Ditton, where the water would be received by the companies and pumped for the supply of the town.

The estimated cost, including the purchase of the canal, is set down by Mr. Hennell at 280,000*l.*

Mr. Ewens' Plan.

3685 et seq. 79. Mr. G. W. Ewens points out the existence of certain springs in the chalk from Emsworth to Bedhampton near Chichester, from which he believes a large quantity of pure water might be obtained of a quality very similar to New River water. He mentions springs of this kind at Emsworth, Havant, Bedhampton, Brockhampton, and Langbourne, and adds:

3699. "There are six streams formed by nine separate series of springs; each of these streams flow into the sea at an average distance of half a mile from the spot from whence they take their rise. There are eight flour mills driven by these six streams."

The water might be pumped into large reservoirs on Portsdown Hill and near Petersfield, and conveyed by a conduit to London.

Mr. Telford McNeil's Plan.

5815 et seq. 80. Mr. Telford McNeil proposes to give a supply of 200,000,000 gallons daily by intercepting water from the Thames at Teddington, raising it 200 to 380 feet, and conveying it in an open channel to the Bagshot sands, through which it is to be made to filter, and from which it is to be conveyed back in a closed conduit to London, and

again pumped into reservoirs at Norwood and Hampstead. The estimate is something above 6,000,000*l.*

Remarks on the above-mentioned Plans.

81. The chief feature of Mr. McClean's plan is the mode by which he proposes to effect the storage in the Thames, and this may deserve consideration whenever it may be found necessary largely to increase the quantity of water drawn from the river. The plan for taking the water from Medmenham would be very expensive, and, probably, of doubtful utility as regards quality (for reasons that will hereafter be shown), while it would be open to the objection of depriving the 37 miles of river between Medmenham and Hampton of a large proportion of its dry weather volume.

The plan of Mr. Bailey Denton, a gentleman of very large experience in drainage matters, is remarkable on account of the manner in which he proposes to deal with the sewage. His opinions also as to the mode of increased storage are valuable.

Mr. Brown and Mr. Bravender point to the value of the springs in the oolites as subsidiary sources of supply.

The plan of Mr. Mylne for increasing the supply from the Lee presents some ingenious and novel features. By the proposed mode of collection he would obtain the water in a state of greater purity than at present, while the mode of storage also claims advantages over former plans. We question whether the quantity Mr. Mylne estimates could be rendered available in the driest seasons, but if any measures should be considered desirable for enlarging and improving the supply from the Lee, his plan would deserve consideration.

With respect to the water sources in the chalk formations we shall speak more at length hereafter. Mr. Meeson's springs at Grays deserve special mention on account of the practical use already made of them by him.

Mr. Hennell's plan has some novelty, but the water might probably be more advantageously utilized for other towns nearer the line of canal.

Mr. Ewens calls attention to some fine springs; they are too far away to be of use for London, but might probably be of value to towns in the neighbourhood.

GENERAL REMARKS ON THE SOURCES AND SPRINGS IN THE THAMES BASIN.

82. It may now be well to review all the resources of the Thames basin before we proceed to consider the important question of the future supply of the metropolis.

83. In order to explain the geological and physical features of this tract of country we have had prepared the large map of the Thames basin marked Appendix Y (1). It is drawn on the scale of six miles to an inch; it shows by colours the various geological formations; and it has contour lines marked upon it at every 100 feet difference of altitude, by which the levels of the ground at the various parts of the basin may be seen. Another corresponding map, Appendix Y (2), has the contours shaded, by which the varying elevations of the ground are made more distinct.

84. The drainage of the Thames valley above Kingston extends over 3,676 square miles; this area receives an average annual rainfall of about 27·2 inches, and one-third of the quantity due to this rainfall flows down the Thames at Hampton.

This delivery is the result of very complex conditions. One third of the area consists of impermeable clays, and two-thirds (or about 2,450 square miles) of permeable oolitic limestones, sands, and chalk. From the former, the rainfall, after allowing for evaporation and for vegetation, flows off at once, and whenever in excess gives rise to floods, whereas the rainfall on the latter is at once stored up, and its ultimate delivery through springs to the streams and rivers is spread over weeks or months. To this cause is owing the permanence of flow of a river draining a permeable rock district, compared with the irregular delivery of a river draining an impermeable district, and it is a consideration of great importance in a question of water supply.

85. In order to indicate the extent of the underground reservoirs formed by the permeable strata, and the sources on which the springs depend for their supplies, we have constructed a series of sections, shown in Appendix Y (3). A complete and elaborate survey would be necessary in order to give the exact lines, whether of the surface of the ground or of the levels of the underground water, but these sections will serve to give an

idea, sufficiently approximate for our object, of the extent and capacity of the underground reservoirs on which the streams depend for their supplies during periods of drought.

86. All permeable formations tend necessarily, by the absorption of rain, to become charged with water up to the level generally of the streams and rivers of the district; and further, owing to the resistance experienced by the rain water in passing through the strata, the water, wherever the ground rises above the level of the rivers, accumulates therein in proportion to the length, breadth, and height of the range of hills, so that instead of the line of underground water level presenting a flat surface between two valleys, it presents a curved surface varying according to certain conditions. Taking the lowest point of escape as determining the permanent level above which all the water tends to run off in springs, the height of the curve above this level gives the head of water on which the springs depend for their supply. The rise of the water being from the circumference of the hills to the centre, the underground reservoirs form more or less dome-shaped masses, the surface of which is constantly fluctuating in proportion to the difference between the amount of rain percolating through the strata and the quantity of water which escapes by the springs.

In the district we have to deal with, the crown of the curve often rises 50 to 200 feet or more above the permanent spring levels, while the actual height of the curve is known to vary in accordance with the variation in the rainfall, in many cases as much as 50 to 80 feet or more. Where the conditions are favourable to a large underground reservoir the springs hardly ever run dry. Mr. Beardmore, as the result of many years' observations in the chalk district of the Lee, sees reason to believe that the storing power of the chalk hills there holds out at least 16 months.

The darker water lines in the sections represent the upper portion of the head of water accumulating in the hills, and serving to feed the higher and smaller springs; the next shade shows the larger portion which goes to feed the lower and more perennial springs. The portion of the sections over which the faint water lines extend represents theoretically those portions of the permeable strata which are permanently charged with water, and from which wells can always draw a supply—in sand strata at once, and in the more compact limestones and in chalk as soon as any of the intercommunicating fissures or crevices are reached, unless any excessive exhaustion has produced a local depression of the water level.

Further, some of the water below the lines of permanent level inland has a slow underground movement to still lower levels, unless intercepted or thrown out by faults in the strata or by some other cause. This underground drainage is not, however, coincident with the surface drainage; and while some of the water-bearing strata of the Thames basin are not available as underground sources of supply by means of wells at or near London, other strata, on the contrary, out of the London basin, are so available from the circumstance of the dip of the beds being towards London. The extent of this underground area supposed to centre towards London is represented by dotted lines on the map, Appendix Y (1).

Where the permeable strata only cap the hills the springs issue of course on the sides of the valleys at the junction of the impermeable strata.

87. In the order of superposition the highest permeable strata near London, excluding the superficial beds of gravel, are—

The *Bagshot Sands*, which are from 100 to 350 feet thick and extend over an area of 211 square miles. As these strata consist almost entirely of loose quartzose sands, the underground water oozes out commonly at their junction with the London clay, and is rarely conducted into any particular channel of escape so as to form springs, and the loss by evaporation is large. There are in fact throughout this area no springs of any importance; only a few small tributaries of the Thames and the Wey have their sources in this district, and the supply to the wells is not large. The water generally is soft and pure, but in some places it is ferruginous. We cannot look to these sands for any additional water supply, (although they attracted a good deal of attention a few years since,) for the whole of the water now delivered by them passes into the Thames or the Wey. None passes elsewhere underground.

The *London Clay* underlies the Bagshot sands and forms a great impermeable bed from 400 to 450 feet thick.

Lower Tertiary Sands.—These beds, which are only from 50 to 100 feet thick, are of no importance so far as springs are concerned at their outcrop, but they have been useful sources of supply to some of the deep wells under London. Owing, however, to the great increase in the number of these wells, and the fall in the level of the water, the

underlying chalk is now generally resorted to as the better source of supply. In many places round London where they have not been so drawn upon they still yield a good supply of water.

88. The *Chalk*, from its large area (1,047 square miles above Kingston, but more than double that in the whole basin); from its great thickness—500 to 1,000 feet—and from its peculiar lithological character, forms a very important source of water supply, both by springs and by means of wells. Almost all the rain falling on its surface is absorbed or percolates through the fissured surface. So close is its texture that the bulk of the rain takes weeks and months to filter down to the level of the water line in the interior of the chalk hills—a line the depth of which below the surface of the ground may vary from 100 to 300 feet according to the height of the hills. The water thus stored escapes in several ways—some by the streams rising within the chalk district,—some by springs feeding directly the larger rivers flowing through it,—another portion overflows at the outer escarpment of the chalk,—and a larger portion issues near its junction with the tertiary strata. A certain quantity also passes underground, supplies the wells, in the central tertiary area, and escapes in part at still lower levels at more distant points.

Where the rise of the bottom of the valleys is more rapid than that of the line of water level, the valleys assume the character so common in chalk districts, of dry valleys. Others of these valleys tap the springs in their lower part, whilst the upper part of the same valley is dry. In these cases the head of the stream will often change its position two or three miles higher or lower in the valley, accordingly as the rise and fall of the water level in the hills are influenced by the rainfall. Where the deeper and larger river valleys traverse the chalk area and intersect the line of water level, these valleys become fringed on the river level with a series of springs, as the Thames in its course from Wallingford to Taplow, the Lee above Broxbourne, the Ravensbourne, the Cray, and the Darenth, and the Thames again from Woolwich to Gravesend.

The springs along the line of outcrop of the chalk marl and gault being on a higher level than any others, the head of water supplying them is much smaller than that supplying the springs on lower levels within the chalk area, and consequently with few exceptions these springs are small. They are, however, extremely numerous. Almost every little village under the range of the chalk downs in Wiltshire, Oxfordshire, and further eastward, has its spring near the foot of the chalk hills. These collectively would furnish a considerable quantity of water, but they are too scattered and wide apart to be available for any general purpose. There are, however, a few large springs amongst them. There is one, for example, at Cherhill near Calne. This spring never fails, and is said to yield from two to three million gallons of water daily. It is represented at the end of section No. 4, Appendix Y (3). There are also copious springs near Ellensborough, at Barton-in-the-Clay near Prince's Risborough, near Swindon, and at many places along the foot of the North Downs of Kent and Surrey.

Another and more important class of springs are those which escape along the inner edge of the chalk along or near the line where it passes under the tertiary strata, and again where it approaches the sea level. These springs are all placed on relatively low levels, and derive their supplies from the large head of water which extends in the chalk hills beyond them up to the outcrop of the beds underlying that formation. As the difference of level between these exterior and interior springs varies often from 150 to 300 feet, the latter are necessarily much more powerful and permanent, and will continue to run long after most of the others have become dry. Among the more copious and remarkable springs of this class are those at Chadwell near Ware, Otter's pool near Watford, Froxfield near Hungerford, Beddington and Carshalton, Orpington, Grays Thurrock, Springhead near Gravesend, Ospringe near Faversham, besides a number of smaller ones. The origin and source of supply of some of these springs are indicated in the sections.

In the neighbourhood of London the wells in the chalk form an important auxiliary source of water supply, and they might, no doubt, be considerably increased in Kent without interfering with the springs in the valleys above London, as the store from which those wells draw their supplies overflows in numberless springs along the Thames below London at levels where they are not generally available.

The lower beds of the chalk are so argillaceous as often to hold up the water and to lose their ordinary permeable character.

89. The *Upper Greensand* forms so much a part of the lower chalk, and is so slightly developed near London, that we have grouped it with the chalk. It is only in Wiltshire that it acquires an importance entitling it to be considered apart. Under London it becomes also so argillaceous as to lose its water-bearing character.

The upper and lower Greensands are separated by 100 to 200 feet of impermeable clay, known as the *Gault*. The numerous small streams rising at the foot of the chalk hills have their source generally in springs thrown out by the chalk-marl, or the gault.

The *Lower Greensands* form a mass of siliceous sandy strata from 200 to 500 feet thick, and with an available area of above 500 square miles. Cropping out both to the north and south of London conformably to the chalk, which is known to pass below the tertiary strata under London, it was supposed that the Lower Greensands were also continuous below London, in the same way as the Lower Greensands of the plains of Champagne pass under Paris at the depth of 1,800 feet. The experience, however, obtained at Kentish Town, at the deep well sunk through the chalk a few years since by the Hampstead Company, showed that although the tertiary strata, the chalk, and the gault followed in regular order, a change took place at the base of the gault, and instead of the lower greensands, a series of red and grey sandstones were met with. These were bored into for a thickness of 188 feet without passing through them and the work was abandoned. (Appendix, Y 3, Section No. 2.) No organic remains were discovered to indicate the age of these sandstones, and the hand specimens were insufficient to determine the question. They may have belonged to some member of the New Red Sandstone, or possibly to the Old Red. In any case they seem to form part of an underground ridge of old secondary or palæozoic rocks which, ranging from Belgium, pass under the chalk at Calais and Harwich, at both which places they have been met with, and probably extend under London in the direction of Somersetshire. The width of this belt can only be determined by experiment.

It is known that the Lower Greensands exist at Reigate and are about 450 feet thick, and that they occur again in Bedfordshire with a thickness of about 200 feet. In both cases they dip towards London, disappearing beneath the gault. We know that they do not exist under London (Kentish Town). It follows, therefore, that in the one case they cease at some point between Reigate or Merstham and London, and in the other between Baldock and London. As at both ends they are of considerable thickness, and the gault is continuous, it is certain that the greensands must range from these outcrops some way towards London, probably thinning off gradually against the flanks of the underground ridge of old rocks. So far as they continue, so far will they form a valuable and copious water-bearing bed, the water from which would overflow at the levels lower than that of their outcrop. The extent of their underground range could only be determined by boring. It might be as far as Croydon, or even still nearer to London. The same would happen to the north of London, but the distance there is greater, the beds are not so thick, and the conditions generally are less favourable. The great purity of the water from the Grenelle and other artesian wells in the Lower Greensand is well known, and there is reason to suppose that the quality of the water obtained from the same formation in the vicinity of London would prove equally good. The excessive length of filtration would at all events ensure freedom from organic impurities.

The quality of the water flowing from the Lower Greensands is excellent for all domestic purposes, being bright and limpid, of a degree of hardness varying only from about 3° to 9 of Clark's test, and generally very free from organic matter. A considerable amount of evidence on the quality of this water was collected by the Board of Health in 1850.

The springs in this formation are not very numerous, owing to the prevalence of sandy beds, but in some of the more stony beds there are some fine springs, as for example:—

1. The springs in Bradbourne Park and at Riverhead near Sevenoaks.
2. Several springs near Dorking.
3. Spring at Weston Street.
4. Spring at Moorhead Park near Farnham.

90. To the south of London a great thickness of *Weald clay* separates the Lower Greensand from the *Hastings sand* of the weald of Kent and Sussex; but although these beds are thick they are very local, only partially permeable, and are of no avail.

91. The strata which next succeed are only developed in the north and north-west of the London basin.

The *Portland Stone and Sands* are from 35 to 50 feet thick, and are, in some places, of local importance, but none of the springs would be available for distant purposes.

The *Kimmeridge Clay* is impermeable and from 250 to 300 feet thick.

The *Coral Rag* and *Calcareous Grit* are from 20 to 50 feet thick and give rise but to a few small springs. These beds thin off as they range to the east and south-east, so that in Buckinghamshire and probably underground in Berkshire the Kimmeridge and Oxford clays come into contact, and the coral rag ceases to exist.

The *Oxford clay* is impermeable, and attains in Oxfordshire a thickness of 400 to 500 feet.

92. The *Great Oolite* and subordinate beds may for our purposes be taken together. They form in Oxfordshire an important group of permeable strata 250 to 300 feet thick. They have a collecting area of about 300 square miles, and give rise to a number of fine springs, amongst which those of Ampney, Bibury, Boxwell, and Thames Head have been described by Mr. Bravender and Mr. Brown, and are stated by Mr. Pole to have been yielding at the time of his visit probably not less than 10 million gallons of water daily.

Most of the springs of this series are thrown out by the *Fullers Earth*, an impermeable bed of no great thickness in this district—40 to 60 feet—and persistent only over a limited part of the area. (See section No. 3.)

The *Inferior Oolite* and underlying sands reposing on the lias form another important water-bearing formation. They are from 300 to 320 feet thick, and extend in the Thames basin over about 180 square miles. As the hills of this formation rise 230 to 300 feet above the valleys and have a considerable range, the head of underground water is large and furnishes several important and perennial springs, such as those of Syreford, and the Seven Springs, of which the yield is stated by Mr. Pole to have been at the time of his visit from three to four million gallons of water daily. (See section No. 3.)

These various oolitic strata consist of beds of rubbly limestones, soft freestones, sands and fissile sandstones, through which the water passes chiefly by fissures; and although often traversing a great thickness of strata, it is not filtered to the same extent as it is in the chalk and Lower Greensands.

Mr. Hull has shown* that the inferior oolite and underlying sands, which in the neighbourhood of Cheltenham are about 320 feet thick, thin off as they range eastward, and probably die out about the centre of Oxfordshire. In the same way he shows that the great oolite and accompanying beds, there about 300 feet thick, also thin to the eastward, and they apparently do not extend more than a few miles further east than the inferior oolite.

It follows that the underground passage of water through these oolites, which might, had these formations ranged in full force eastward, have been carried as far as London, the dip being in that direction, is stopped by the thinning out of those beds, and by the closing in, as it were, of the Lias, Oxford clay, and Kimmeridge clay. Although, therefore, the surface drainage of the Cirencester and Bampton districts runs into the Thames valley, the subterranean water channels are intercepted and do not reach London, and the oolitic series must be excluded as a possible source of supply by deep wells in the London district.

93. The exact proportion of the rainfall absorbed by the different permeable and porous strata, and which is given out again in the form of springs, yet has to be determined. It varies according to the lithological character of the water-bearing strata. The general results are, however, known in many cases. Thus the annual flow of the Thames at Hampton and of the Seine at Paris, both draining areas composed partly of permeable and partly of impermeable strata, is equal to about one-third of the rainfall. In a district where the impermeable strata predominate, the total deliveries will be larger, but they will follow close upon the rainfall; whereas, as the permeable strata predominate, so will the rainfall be stored in the hills, and its delivery be spread over a greater length of time. The summer flow in a dry season consists almost entirely of the supplies derived from deep-seated springs. Mr. J. T. Harrison, to whose evidence we would refer for many interesting details on these points, estimates this generally in the Thames district to be equal to one-sixth of the rainfall.

94. The importance of such a condition of things for the supply of this large metropolis cannot be over-estimated. It ensures that permanence and regularity which are necessarily among the most important elements in a metropolitan water supply. With natural subterranean reservoirs extending over above 2,000 square miles, a storage reserve is provided comparatively independent of the seasons, and maintained by the ordinary operations of nature, while no filtration can equal that effected through masses of sand, sandstone, earthy limestones, or chalk, from 50 to 300 feet thick. The quantity of mineral matter taken up is in most cases moderate, while the really objectionable ingredient—the organic matter—is reduced to a minimum. However different the results obtained in

* Quart. Journ. Geol. Soc., vol. xvi. p. 63.

other cases, the two under-mentioned eminent chemists agree in their conclusions on this point, as will be seen by the following table, the quantities having reference in the first case to 100,000 parts, and in the second to a gallon of water:—

	Dr. Frankland.			Prof. Wanklyn.
	Organic Carbon.	Organic Nitrogen.	Nitrogen as Nitrates and Nitrites.	Albuminoid Ammonia (representing the Organic Matter containing Nitrogen).
Caterham well (chalk)	·020	·006	·027	0·000
Spring near Moor Park (lower greensand)	·030	·010	·045	—
Cold Harbour (lower greensand)	—	—	—	0·000
Otter Spring (chalk)	·026	·012	·422	—
Loch Katrine	·256	·008	·031	0·130
Welsh waters	·289	·004	·022	—
Cumberland Lakes	·211	·006	·009	—
Thames water at Hampton	·260	·024	·192	0·134

At the same time the water is kept at a uniform low temperature and protected from light and air, conditions unfavorable to the existence of living organisms. Springs from such sources probably represent potable waters in their best state; and amongst the favourable specimens of such waters may be instanced many chalk springs, the water from the lower chalk at Caterham, and some of the springs of the Lower Greensands of Surrey.

It is satisfactory to know that there exists within easy reach of London a supply of the best and purest spring water which, in case of need, could readily be rendered available as an auxiliary source of water supply for the metropolis, in quantity sufficient at all events for drinking, if not for other purposes.

PART III.

ON THE PRESENT WATER SUPPLY OF THE METROPOLIS.

95. We now proceed to consider "the present water supply to the metropolis."*

We have accounts of the existence, at a very early date, of artificial works for the water supply of London, in the form of certain conduits, some of whose names still survive in *Conduit Street*, *Lambs Conduit*, and *White Conduit*, and the object of which was to bring for the use of the inhabitants the waters of local springs; but about the middle of the sixteenth century the metropolis had so increased in extent that these were no longer sufficient, and attention became directed to procuring supplies, by mechanical means, from the fine river running close to the city walls.

96. The first systematic attempt to supply London from the Thames was made by Peter Morrys, an ingenious Dutchman, who in 1581 obtained the consent of the corporation to erect a water-wheel under one of the arches of London Bridge; this, being turned by the tidal stream, worked forcing pumps, which impelled the water through the leaden or wooden pipes in the streets, and thence by branches into the houses. The *London Bridge Waterworks*, thus established, subsequently increased in magnitude, and kept up a considerable supply for two hundred years.

97. But as London extended, Morrys's mains and pumping power were, in that infant state of hydraulic science, insufficient to supply the higher and more remote parts of the town, and attention became redirected to sources inland. In 1606 an Act of Parliament was obtained to enable the corporation to bring a stream of clear pure water to the metropolis, from certain copious springs in the chalk at Chadwell and Amwell, near Ware; but the corporation, alarmed probably at the magnitude of the plan, hesitated to commence the works, and nothing was done until, in 1609, an enterprising citizen, Mr. Hugh Myddelton (afterwards Sir Hugh Myddelton, baronet) offered to execute them single-handed, on condition that the authority obtained from Parliament should be transferred to him. This offer was accepted, and he at once commenced the work; but through a complication of difficulties, and the refusal of the corporation to aid him (although he had brought his canal to within a few miles of London), he was compelled to appeal to King James I. for the means of completing his work. The King furnished the necessary grant of money on condition that half the property in the undertaking should be ceded to him, and in September 1613, the canal, then dignified with the name of the *New River*, was completed, conveying the pure Hertfordshire spring water into the reservoirs at Clerkenwell. Thus was introduced into the metropolis a true systematic "water supply by gravitation," after the manner of the ancients.

98. The New River and the London Bridge works, aided by the local springs, with many public pumps and shallow wells, kept the greater part of the metropolis well supplied with water for the whole of the seventeenth century; but as buildings began to extend westward new demands arose. Soon after the opening of the New River, the chalk springs had been supplemented by tapping the River Lee, near to them, but parts of London required water where the London Bridge and New River mains did not reach, and again the Thames was resorted to for an increased supply. In 1691 a company was formed, called the *York Buildings Waterworks Company*, for supplying a part of Westminster with water pumped from a point in the river near Charing Cross. These works flourished for some time, but were in 1818 leased to the New River Company, and in 1829 were abolished altogether.

In 1723 a more successful attempt was made in the establishment of the *Chelsea Waterworks* for supplying Westminster and the parts adjacent with water from the Thames at Chelsea Reach. The company first purchased some small works at Millbank, but afterwards removed to a site near the foot of the present Victoria railway bridge, where they erected a pumping establishment.

* The information in this part, where not obtainable from official documents, has been taken from Mathews's "Hydraulia" and Weale's "London in 1851," or gained by communication with the officers of the companies.

99. The portion of the metropolis south of the river was supplied at a very early date by two wheels erected under London Bridge near the Surrey shore, and by separate works not far distant.

In 1785 the *Lambeth Waterworks Company* was established for supplying the parish of Lambeth and parts adjacent with water pumped from the Thames at a site opposite Charing Cross.

100. During the eighteenth century the existing waterworks were gradually enlarged and improved, and iron street pipes were introduced in lieu of wooden ones, a change which not only enabled the old works materially to extend their supplies, but gave a great advantage to new companies entering the field in competition with them.

101. In 1806 the *West Middlesex Water Company* was established for supplying the western suburbs from the Thames at Hammersmith; and in 1811 another company was formed who availed themselves of power granted by a clause in the Grand Junction Canal Company's Act for supplying, to the north-west of London, water brought by the canal from the rivers Colne and Brent, and from a large reservoir supplied by land drainage in the same neighbourhood. These waters were represented to be much superior to that of the Thames; but experience disappointed the hopes of the projectors; the water was found not only bad in quality, but deficient in quantity; and after vain expedients to remedy the evils, the company, which had taken the name of the *Grand Junction Waterworks Company*, resorted in 1820 to the Thames, taking their entire supply from a point near Chelsea Hospital.

102. While these works were going on in the west, the inhabitants of the other part of the metropolis had not been idle. The districts eastward, beyond the reach of the mains of the New River or London Bridge works, had hitherto been dependent on two small establishments at Shadwell and West Ham; but as the population increased, and further supplies became necessary, a company was established under the name of the *East London Waterworks Company*, for supplying water from the River Lee. Their Act was obtained in 1806; they immediately erected works at Old Ford, near Bow, and soon spread their mains over an extensive district.

In the south districts a new company was established in 1805 called the *Vauxhall Waterworks Company*; they took water from the River Effra, and afterwards from the Thames near Vauxhall Bridge. In 1822 the two ancient establishments at and near London Bridge, supplying Southwark, were combined under the name of the *Southwark Waterworks*.

103. By about the year 1820 the various water companies whose rise we have chronicled above had established a firm footing, and rendered themselves necessary to the inhabitants of London, in respect of the supply of this vital element of health. But the records show that no sooner did they become aware of this fact than they began to take advantage of it for their own interest, by combining together to raise their rates. The public complained loudly of this, and in 1821 a Committee of the House of Commons was appointed to inquire into the whole subject. They made a comprehensive report, in which, while they admitted that "a material improvement had taken place in the supply, both in "respect of abundance and certainty," they recommended that the maximum rates to be charged should be settled by Act of Parliament, and other salutary regulations enforced. No legislation followed this, but it seems to have had its effect in inducing the companies to remove the chief causes of complaint.

104. In a few years, however, discontent arose on another ground, namely, as to the *quality* of the water. The companies had hitherto pumped it into the districts just as it came to hand, without being over particular as to the state it was in. But it was seen that the water of the river was dirty and turbid, and an alarm arose that it must be unwholesome. Accordingly, in 1828, a Royal Commission consisting of three eminent scientific men—Mr. Telford, civil engineer, Professor Brande, chemist, and Dr. Roget, secretary of the Royal Society—was appointed to inquire into "the description, the quality, "and the salubrity of the water" supplied to the metropolis. They had careful examinations and analyses made, from which it appeared that the Thames water when free from extraneous substances was in a state of considerable purity, containing only a moderate degree of saline contents, and those of a kind which could not be supposed to render it unfit for domestic purposes, or injurious to health; but as it

approached the metropolis it became loaded with a quantity of filth which rendered it disgusting to the senses and improper to be employed in the preparation of food.

It appeared, however, that a very considerable part, if not the whole, of this extraneous matter might be removed by filtration through sand, and the Commission took into consideration various plans for effecting this object, which led them to the opinion that it was perfectly possible to filter the whole supply with the requisite rapidity and within reasonable limits of expense.

The general conclusion of the Commission is expressed in the following paragraph:—

"Taking into consideration the various circumstances to which we have now adverted, together with the details of evidence by which they are proved and illustrated, and also the facts derived from our own observation and experience, we are of opinion that the present state of the supply of water to the metropolis is susceptible of, and requires, improvement; that many of the complaints respecting the quality of the water are well founded, and that it ought to be derived from other sources than those now resorted to, and guarded by such restrictions as shall at all times ensure its cleanliness and purity."

From other passages in the report it is clear that the Commission attributed the pollution of the Thames water to its reception of the sewage and refuse from manufactories in the neighbourhood of London, operating within the tideway; it does not appear that they contemplated the possibility of any such large measure as the removal of the companies' points of intake above the range of the tidal flow.

105. Stimulated by this report, and alarmed probably at the prospect of a sweeping change of the sources of supply, the companies directed their attention to the purification of the water by filtration. This process had been well known on a small scale as a means of separating from water any impurities held in suspension, but its application to large public works was a novelty. It was soon found that the only appropriate material for mechanical filtration on a large scale was fine sand; but the great practical difficulty was to prevent the sand from becoming clogged, and to find an easy, practical, and cheap method for its renewal. After much consideration and long-continued experiments a means was discovered of getting over these difficulties. It was found that by far the greater quantity of the impurities were held in suspension by the agitation and motion of the water, and that if it was allowed to stand for some time at perfect rest, in a reservoir, the heavier and grosser particles were deposited by simple subsidence, leaving only a small proportion of lighter and finer matters to be dealt with by filtration. It was also found that when the water was allowed to filter downwards through a porous bed of sand, held up in its place by underlying layers of coarse gravel, the dirt did not penetrate into its mass, but was stopped at the upper surface, so that the whole cleaning operation necessary was to scrape this surface off to a slight thickness, and when it had become too much diminished to put fresh sand on.

The plan of filtration thus matured was at once carried into practice. The first large filter, of one acre area, was set to work by the Chelsea Company in 1829. It was found to work well, and the principle has since been universally adopted.

The other companies, though they did not all adopt the new principle of filtration, made improvements in some way or other. The New River Company constructed extensive settling reservoirs, as did also the West Middlesex Company; the Grand Junction Company removed their source of supply from Chelsea to Brentford, and formed filters there; the East London went higher up the Lee; and the Southwark and the Vauxhall Companies amalgamated, abolished their old sites, and established new joint works at Battersea. The Lambeth Company also formed elevated reservoirs at Brixton Hill and Streatham, to improve the service generally, and to maintain a supply in cases of fire.

106. It would seem, however, that the public had not full confidence in the improvements thus made, for in consequence of the report of the Commission of 1828 the House of Commons recommended that Mr. Telford should look out for new sources of supply, and he was accordingly instructed by the Government to take steps for the purpose. In 1834 he made his report, advising that the northern part of the metropolis should be supplied from the River Verulam above Watford, and the southern part from the Wandle. This report occupied the attention of the House of Commons in 1834, and of the House of Lords in 1840, but nothing was done.

107. The system of filtration was found to work well, so long as the impurities it professed to remove were only mechanical, and were not too great in amount; but it was found that the state of the river was gradually deteriorating, and, what was more

important, that it was becoming fouled in a way that filtration was powerless to purify, namely, by contamination of a chemical nature.

Drainage and sewage works were beginning to be more developed; ideas of what is now called sanitary science were arising; cesspools were beginning to be abolished; and as a consequence much larger quantities of sewage matter began to be poured into the river on all parts of its passage through London. These impurities were carried backwards and forwards by the tide, and their evil effect on the state of the river was enhanced by another circumstance which took place about this time, namely, the introduction of the small local steam boats plying on the Thames above London Bridge, the agitation caused by which not only kept the infused matter in continual mixture with the water, but washed and stirred up the mud at the bottom, which had before lain undisturbed. It was seen that these evils would go on increasing, and would shortly render the water so contaminated as to be beyond the possibility of purification by ordinary means.

108. The first steps towards meeting this difficulty were taken by the Lambeth Company. They had hitherto drawn their water from a site where the bad state of the Thames made itself very obvious, and after well considering the matter, they came to the decision that no measure short of the removal of the source of supply to a point above the highest range of the tide (Teddington lock) would be of any permanent benefit to the quality of the water. They therefore selected a point of the Thames a little above Kingston as their new source, proposing to establish large pumping engines there, and to force the water along a large main of ten miles in length to their existing reservoirs on Brixton Hill. An Act authorizing the works was obtained in 1848, and in 1851 the supply from the new source was delivered to the consumers.

109. Meanwhile the subject of the metropolitan water supply had been taken up by a public body who at that time assumed authority on all matters of a sanitary nature—the General Board of Health. In May 1850 this board issued a long report on the subject, which was followed shortly afterwards by numerous appendices and documents in explanation and justification. They pointed out the evils of drawing water from the Thames within the tideway, where it was exposed to sewage contamination; but not content with this, they objected to the Thames altogether, on the ground of its hardness, as they had adopted the idea that only very soft water was fit for public consumption. They therefore made a recommendation in the following terms:—"Whilst we believe "that Thames water, taken up beyond the influence of the metropolitan drainage, and "filtered, may be used without injury to the public health, and may be employed "temporarily until other sources can be laid under contribution, we advise that Thames "water and other water of like quality as to hardness, be as early as practicable "abandoned." The Board further directed their attention to finding other sources in substitution for the Thames, and fixed upon a tract of ground, of 150 square miles area, formed by the Bagshot sands and the lower greensands in Surrey, from the drainage of which they recommended that the supply for the metropolis should in future be taken.

110. This report was considered by a Committee of the House of Commons in the same year, but they did not endorse the opinions it contained. It happened that about the same time a company was projected, called the London Spring Water Company, which, on the strength of a favourable report made about ten years before by Mr. Robert Stephenson, proposed to supply the metropolis with spring water from the chalk in the neighbourhood of Watford. The Government, distracted by conflicting opinions, and desiring better evidence than they were yet in possession of, at the beginning of 1851 appointed a commission of three eminent chemists, viz., Professor Graham (now Master of the Mint), Dr. Miller, and Dr. Hofmann, to investigate the quality of the water actually supplied, referring to them also the proposals of the Board of Health and of the Watford Company. The report of this Chemical Commission was given in June 1851. It is a most able document, and as it treats of various matters connected with the subject in a manner which, even at this distance of time, is very pertinent to our inquiry, we shall have occasion often to refer to it hereafter.

The Commission expressed their opinion that the Thames water was perfectly wholesome, palatable, and agreeable; uniform, plentiful, and safe in use; but they recommended that to avoid the liability to contamination by the London sewage, the supply should be drawn at a point above the tidal range. They reported unfavourably of the Board of Health scheme, but drew particular attention to the proposed supply from the chalk at

Watford, which, assuming that the hardness could be got rid of by a softening process suggested by Dr. Clark, they considered much preferable to any other from its greater purity.

111. The result of all these investigations was to lead the Government to the opinion that legislation on the subject was desirable, and in 1851 they introduced a Bill to amalgamate all the companies into one great whole, whereby improvements might be introduced more effectively and economically than by dealing with them singly. It was to be one condition that the new company should be compelled to obtain water from such sources as the Secretary of State might direct.

This proposition, which was long and ably fought between its supporters and the companies, also proved too sweeping for the acceptance of the Legislature, and it was modified, the following session, into an Act (15 & 16 Victoria, cap. 84), which, while it did not interfere with the property of the companies, imposed on them many new and important conditions.

112. It is this Act which now regulates the general water supply of the metropolis. It is entitled "An Act to make better provision respecting the Supply of Water to the "Metropolis," and it received the royal assent the 1st of July 1852. Its principal provisions are as follow:

Clause 1 provides that it shall not be lawful for any company supplying the metropolis to take water from any part of the Thames below Teddington lock, or from any part of any of the tributary streams within the range of the tide.

Clause 2 stipulates that every store reservoir within five miles of St. Paul's shall be covered; and Clause 3 makes the same provision for aqueducts, unless the water is subsequently filtered.

Clause 4 provides that all water supplied for domestic use shall be effectually filtered, unless it be pumped from wells direct into covered reservoirs.

Clauses 15 and 22 provide for a constant supply at high pressure being given where demanded by four fifths of the inhabitants of any district, on certain conditions being complied with by them.

Clause 16 makes any company liable to a penalty of 200*l.*, and 100*l.* per month in addition, for violation of the Act, or neglect to comply with its provisions.

The other clauses are of minor importance to our present inquiry.

113. After the passing of this Act the water companies proceeded to comply with its more important provisions, expending about 2,500,000*l.* in works for this purpose; and in 1856, the Government caused chemical and engineering examinations to be made, under the direction of the General Board of Health, to ascertain the results of the changes. The chemical report was made by Professor Hofmann, and Mr. Lindley Blyth, and it showed that while the hardness and solid contents of the water remained about the same, there was a very positive and considerable diminution in the amount of organic matter. This, though doubtless due chiefly to the removal of the intake above the tideway of the Thames, was also attributed in great degree to the considerable improvement which had taken place in the collection, filtration, and general management of the supply of water. The engineering report made by the inspectors of the Board of Health gave a satisfactory account of the new works of the various companies, and of the manner in which they had carried out the provisions of the Act of Parliament. It was suggested, however, that further inquiry should be made into the removable causes of contamination of the Thames above the new sources of supply, and the inspectors recommended the introduction of the constant service system.

114. London is now supplied with water by eight companies, five on the north side of the river, viz.,

The New River Company,
The East London Company,
The Chelsea Company,
The West Middlesex Company,
The Grand Junction Company;

and three on the south side, viz.,

The Lambeth Company,
The Southwark and Vauxhall Company,
The Kent Company.

Each of these companies supplies a certain district, marked by definite boundaries, the whole metropolis being mapped out between them. These districts, together with the sites of the principal pumping stations, filters, mains, and reservoirs, are shown in colours on the map attached to this Report, and marked Appendix AV.

Formerly different companies were often engaged in competition with each other over the same ground; but this course, while it produced no substantial good to the public, was so hurtful to the companies themselves, that it was put an end to by separate limits being assigned to the operations of each company.

115. The *New River Company* supply a very large district, comprehending the whole of central London. The western boundary is a line drawn from Charing Cross by the Haymarket, Tottenham Court Road, and Hampstead Road, northwards to Highgate; the eastern boundary is a line running directly north from the Tower to Stamford Hill.

This company derive the great bulk of their water from sources in the valley of the River Lee, near Hertford, namely,

1. From a copious spring called the Chadwell Spring, situated between Hertford and Ware.
2. From wells sunk into the chalk at Amwell, near Ware, and at Hoddesdon and Cheshunt, a little lower down the valley.
3. From the River Lee itself, in the same neighbourhood.

The waters from these sources are united and conveyed to London by an artificial channel, called the "New River." The distance of the sources from London in a direct line is about 20 miles, but as the New River winds considerably, in order to take advantage of suitable levels of the ground, its course is much longer. The original length was nearly 40 miles, but it has been lately shortened by extensive cuts, leaving its present length only about 28 miles. It is an open river, protected by fencing, for about 25½ miles of its course, the remainder being tunnel or pipe.

The average dimensions of the New River are about 18 feet wide and five feet deep; in its original course it had an average fall of about five inches in each mile of length; but the diminution of length has given a much greater proportionate fall, and has consequently much increased the quantity of water it is capable of conveying.

Leaving Ware, the New River turns southward, and passes through or near Broxbourne, Cheshunt, Enfield, Winchmore Hill, Hornsey, Stoke Newington, Ball's Pond, and Islington, to a site at Clerkenwell known by the name of the New River Head. The water is allowed to subside in reservoirs at Stoke Newington and Clerkenwell, having a joint area of 43½ acres. In addition to the supply brought by the New River, the drainage of a small district, of three or four square miles area, is collected by two reservoirs at Cheshunt of 18½ acres area; this water is admitted into the New River as required. The filtering reservoirs are at Stoke Newington, Hornsey, and Clerkenwell, and occupy 11¼ acres.

At Stoke Newington, Hornsey, and Clerkenwell, there are large pumping engines for forcing the filtered water into store reservoirs at a higher level, situated at Claremont Square and Maiden Lane; and near the Archway, Highgate, is another pumping station, which forces water into still higher reservoirs at Highgate and Hampstead. These reservoirs contain in the aggregate about 20 millions of gallons, and are covered in as required by the Act.

From these reservoirs the district is now supplied, and to meet the varieties of level in the several localities, the district has been divided into several distinct levels, each having its own reservoirs and separate systems of supply. The whole pumping power of the company amounts to nearly 1,700 horses. The length of their mains is about 620 miles.

The company have an engine at Tottenham, by which they can, when necessary, obtain water directly from the Lee, taken at the same point of the river as the water of the East London Company; but this is only intended to be used in case of emergency, such as accident, or stoppage by frost, &c. They have also power to draw water from the Thames below Blackfriars Bridge, to be distributed by separate mains for street watering and sewer flushing, the use of this for the general supply being forbidden by the Act of 1852. It is stated that neither of these supplementary supplies has been used for several years.

The company have further a deep chalk well in the Hampstead Road, and also one formerly belonging to the Hampstead Waterworks, taken by them a few years ago; both these wells, though not at present used, are available to increase the general

supply. They also took to the Hampstead Company's springs and ponds at Hampstead and Highgate, the water of which is used only for street watering.

116. *The East London Waterworks Company* supply also a very large area, comprising the whole of London eastward from the boundary of the New River district, and extending from the St. Katherine's docks to North Woolwich, and from the line of the Shoreditch and Kingsland roads to Woodford.

The supply is derived from the River Lee at Higham Hill, in the parish of Walthamstow, about nine miles above the junction of the Lee and the Thames.

The company have reservoirs at Walthamstow containing about 110 acres of water area, and capable of holding 220 millions of gallons, 170 millions of which can be withdrawn by simple sluices, and the remainder by pumping.

From these reservoirs the water passes by a special private canal about $1\frac{1}{4}$ mile in length to the filtering beds at Lee Bridge, which are 13 in number, divided into two series, and having a united area of 12 acres on the surface of the sand; and after filtration it passes to large pumping engines established at two stations, Lee Bridge and Old Ford.

From the universal flatness of the district this company have no elevated reservoir, but the supply is afforded by the continuous working of one or more engines, and the pressure is kept up by high stand pipes attached to the pumping mains.

They are now executing works for bringing an additional supply from the Thames, under powers to which we shall allude more particularly hereafter.

117. *The Chelsea Waterworks Company* supply a district extending from Charing Cross westward to Fulham, and from the Thames northwards to the Uxbridge Road, and comprehending Chelsea, Knightsbridge, the whole of Belgravia and Pimlico, and a large portion of Westminster.

The water is taken from the Thames at a point on the right or south bank, at Long Ditton, nearly opposite Hampton Court Palace, three miles above the highest range of the tide. It is first allowed to subside in reservoirs constructed for the purpose, and then filtered through sand and gravel, after which it is pumped by steam engines through two large cast-iron main pipes, six miles long, to elevated covered reservoirs, containing 20 millions of gallons, on Putney Heath. From this the water flows, by its own gravity, through mains passing over the Thames at Putney into the company's district.

118. *The West Middlesex Waterworks Company* supply a district extending west of Tottenham Court Road and north of Oxford Street, as far as the Edgware Road, and in addition a large western suburban area, including Kensington, parts of Fulham and Brompton, Hammersmith, Chiswick, &c., and as far north-west as Hendon.

The water is taken from the Thames on the north bank, at a point a little above the town of Hampton, and $5\frac{1}{2}$ miles above the termination of the tidal range at Teddington lock. From this point it is passed by pumping power, through a cast-iron main 36 inches diameter, and $8\frac{3}{4}$ miles long, crossing the river to a site at Barnes, from which the company formerly took their supply. Here the water is first allowed to subside in reservoirs of $20\frac{1}{2}$ acres area, and then filtered in five filter beds of about eight acres. It then crosses again under the bed of the river to the north bank at Hammersmith, where the pumping station is situated for supplying the district. There are two elevated covered reservoirs, one at Kensington, containing about $3\frac{1}{2}$ millions of gallons; the other on Primrose Hill, at a high level, containing $4\frac{3}{4}$ millions of gallons. For some parts which lie higher it is necessary again to pump, from Primrose Hill, into another more elevated covered reservoir, containing $2\frac{1}{2}$ millions of gallons, at Hampstead.

119. *The Grand Junction Waterworks Company's* district comprehends that part of the parish of St. George, Hanover Square, which lies north of Piccadilly, a small portion of Marylebone, the larger part of Paddington, and St. James's to Pall Mall.

They take water from the Thames, close to the point of the West Middlesex supply, and force it along a 33-inch main to Brentford, $7\frac{1}{4}$ miles distant. It is allowed to subside in reservoirs partly at Hampton and partly at Brentford, covering $8\frac{1}{4}$ acres, then filtered in beds occupying $5\frac{1}{6}$ acres, and then is pumped into the district, there being an elevated covered reservoir on Camden Hill, Bayswater, containing 6,000,000 gallons, with additional engine power for still higher levels.

120. *The Lambeth Waterworks Company* supply a large district on the Surrey side

extending from the Thames on the north to Croydon on the south, and from Lewisham and Beckenham on the east to Thames Ditton and Esher on the west.

They take their water from the Thames near Long Ditton at the place adopted by the Chelsea Company. Here filter beds and pumping engines are established, forcing the water along a cast-iron main, $10\frac{1}{4}$ miles long and 30 inches diameter, to elevated covered reservoirs at Brixton, containing 12,000,000 gallons; from these it flows by gravity into the whole of the low-lying district, and is again pumped to supply higher covered reservoirs at Streatham, Selhurst, and Rock Hill, the highest service given being at Norwood, about 350 feet above the Thames.

121. *The Southwark and Vauxhall Water Company* supply a still larger district, comprising the borough of Southwark, portions of Lambeth and Clapham, and the whole of Battersea, and extending east to Rotherhithe, west to Richmond, and south to Camberwell. In some parts supplies are given both by this and the Lambeth Company.

They obtain water from the Thames above Hampton, at the same site as the West Middlesex and Grand Junction, and it is forced along a 36-inch main 13 miles long to their old establishment at Battersea, where it is pumped by large engines directly into the district mains; like the East London they have no elevated store reservoirs. There are large subsiding reservoirs and filters, both at Hampton and at Battersea.

122. *The Kent Waterworks Company* supply the whole of the south-eastern suburbs, their district comprising Deptford, Greenwich, and Woolwich, and extending from Camberwell to Dartford, and from the Thames southward to Bromley, Chiselhurst, and Bexley.

This company was incorporated in 1810, when they took possession of some ancient works on the river Ravensbourne at Deptford, established as early as 1699. Down to 1857 they continued to take water only from this source, but the river proving insufficient, the supply was then supplemented by wells sunk into the chalk, and, this source proving so much more plentiful and so much better in quality, in 1862 the Ravensbourne was entirely abandoned.

The principal station is at Deptford, where there are three wells on the site of the old works, each with a pumping engine, the water being conveyed for distribution to other engines, which pump directly into the district mains. There are also two wells at Charlton, one at Plumstead, one at Crayford, and one at Bromley; at each of these wells an engine is placed which serves both for pumping and for distribution.

In addition to the pumping power at the different wells, there are other engines near Shooters Hill for supplying the more elevated districts, and there are elevated reservoirs in Greenwich Park, on Woolwich Common, and at Plumstead and Chiselhurst, to regulate the pressure, and keep up a supply in case of fire. The water does not require filtration.

The following data refer to the wells furnishing this company's supply:—

	Maximum Quantity pumped (Gallons per hour).	Levels with reference to Ordnance Datum, in feet.			
		Of Surface of Ground.	Of Bottom of Well or Bore-hole.	Of Surface of Water when not pumping.	Of Surface of Water when pumping Maximum Quantity.
3 Deptford wells -	287,000	+20	−230	+12	− 44
2 Charlton wells -	70,000	+25	−225	+10	− 45
Plumstead well -	57,000	+80	−420	+10	− 20
Bromley well - -	25,000	+120	−130	+115	+103
Crayford well -	38,000	+30	−120	+20	+ 14

123. In addition to the supplies of the water companies, there is a considerable quantity of water furnished from wells sunk, in 1844, by Messrs. Easton and Amos, on behalf of the Government, near Charing Cross. They are nearly 400 feet deep, penetrating into the chalk, and they furnish a quantity of about 430,000 gallons per day, which is used to supply the Government offices and several public establishments in Westminster and the neighbourhood, and the fountains in Trafalgar Square.

A small further addition to the supply of the suburbs of the metropolis is obtained from the chalk springs at Grays, in Essex, described in Mr. Meesom's evidence, and alluded to in Part II. of our Report. A company was incorporated in July 1861 for this purpose, under the name of the South Essex Water Company, and a pumping establishment was formed at Grays, with a store reservoir at Brentwood, and distributing mains ramifying in various directions. The water is now delivered at Brentwood, Shenfield, Warley (including the great barracks there), Grays, and several neighbouring villages. The quantity pumped is about 450,000 gallons per day, and the number of inhabitants supplied between 15,000 and 16,000.

124. The following table gives the statistics of the principal water companies in a combined form:—

Statistics of present London Water Supply.

——	Capital.	Approximate Area of District supplied.	Number of Houses supplied, 1867.	Estimated Number of Inhabitants supplied, 1867.	Average daily Supply, 1867.
From the Thames.	£	Square miles.			Gallons.
Chelsea Company - -	785,600	6½	26,875	170,000	8,087,258
West Middlesex - -	798,571	10	36,881	275,000	8,816,486
Grand Junction - -	850,000	24	27,190	245,000	9,533,432
Southwark and Vauxhall -	1,100,440	30	71,558	465,000	13,629,758
Lambeth - - - -	736,245	25	38,320	230,000	8,975,530
					49,042,467
From the Basin of the Lee.					
New River Company -	2,609,418	19	113,462	800,000	23,790,667
East London Company -	1,400,000	50	92,652	675,000	19,298,241
					43,088,908
From Chalk wells in Kent.					
Kent Company - -	489,240	60	34,504	240,000	6,468,873
Total -	8,769,514	224½	441,442	3,100,000	98,600,248

In reference to the quantity supplied, it must be observed that the amount in the last column expresses only the average daily supply for the whole year; but a reference to the table in Appendix N will show that, as might be expected, the supply is much greater in summer than in winter. The *maximum* daily supplies in June or July were as follows:—

	Gallons.
Chelsea - - - - -	9,042,800
West Middlesex - - - -	9,776,707
Grand Junction - - - -	11,032,742
Southwark and Vauxhall - - -	13,975,000
Lambeth - - - - - -	10,257,800
New River - - - - -	26,710,000
East London - - - - -	20,321,152
Kent - - - - -	7,196,708
Total - -	108,312,909

This shows that the maximum daily quantity supplied in the summer months is about 10 per cent. in excess of the average of the whole year, and this is an important fact in considerations affecting the quantity of water required.

The following table gives particulars of the reservoirs, filter beds, and pumping engines of the various companies:—

WORKS OF THE COMPANIES.

Subsiding Reservoirs.		Filter Beds.		Store Reservoirs.			Pumping Engines.

125. The distribution of the water is on what is called the *intermittent* system. The supply pipes to the houses are not attached to mains in which the water is always under pressure, but to smaller service pipes, into which the water is "turned on," as it is called, during only one or two hours each day, the consumers receiving during this short time the whole quantity required for the day's consumption, and storing it for use in cisterns provided by themselves. On Sundays, as a general rule, no supply is given, but exceptions are made by many of the companies in poor neighbourhoods where the receptacles are insufficient.

126. We may now allude to the more recent public proceedings affecting the water supply of the metropolis.

In 1865 a Royal Commission was appointed to inquire into the best means of preventing the pollution of rivers, embracing also the question of water supply. In March 1866 they reported on the River Thames; and their report, so far as bears on our present inquiry, was to the effect that the river was at present fouled by various causes, but principally by the sewage of towns, villages, and houses on its banks, but that this sewage might be so utilized on land as to be rendered innocuous. They recommended that the whole river should be placed under the superintendence of one governing body, who should amongst other duties take steps to ensure its freedom from pollution.

This recommendation bore immediate fruit, for on the 6th of August in the same year an Act (29 & 30 Vict. cap. 89) was passed, altering the constitution of the existing Conservancy Board of the Thames, and considerably enlarging their powers. It extended their jurisdiction up to Cricklade in Wilts, and made two important provisions for ensuring the purity of the water:—

1. The surface of the river was to be effectually scavenged, in order to the removal therefrom of substances liable to putrefaction.
2. The admission of sewage or any other offensive or injurious matter into the Thames, or into any tributary stream or watercourse within three miles of its junction with the Thames, was declared illegal, the Conservators giving due notice to all offending parties to discontinue the practice under heavy penalties.

To enable towns and villages more easily to comply with the requirements of this law, there was passed in August of the next year an Act (30 & 31 Vict. cap. 113) for facilitating the distribution of sewage matter over land, and otherwise amending a law previously passed with the same view.

127. In May 1867 the Rivers Pollution Commission made a report on the River Lee, which they found liable to pollution from sewage and refuse from manufactories, and beset with peculiar difficulties as to its purification and general management; they recommended certain measures with a view to improvement.

During the same session, the East London Waterworks Company, who were requiring to increase their supply, applied to Parliament for powers to enlarge their works; and having been led by the experience of the extreme dry season of 1864 to distrust the capability of the River Lee to afford all they wanted, they promoted a bill for enabling them to draw 10,000,000 gallons per day from the Thames at Sunbury. Both these bills were passed, with certain controlling provisions.

It had happened, however, that in the previous year there was a severe outbreak of cholera in the east of London, and, from certain peculiarities in the phenomena exhibited, suspicion was entertained that it might be connected with the water supply. The suspicion was strengthened by the circumstance that the Registrar General for the metropolitan districts had established a monthly analysis of the water supplied, and that his reports had produced an impression unfavourable to the quality. When therefore the East London bill was referred to a Committee of the Commons, the House took the opportunity of instructing them to inquire generally into the operation and results of the Metropolis Water Act, 1852, of which, as it came into full operation in 1856, ten years' experience had been gained.

128. This committee, of which Mr. Ayrton was chairman, inquired fully into the whole subject, and reported at the end of June 1867.

As to the main question, they declared they were satisfied that both the quantity and quality of the water supplied from the Thames were so far satisfactory that there was no ground for disturbing the arrangements made under the Act of 1852, and that any attempt to do so would only end in entailing a waste of capital and an unnecessary charge upon the owners and occupiers of property in the metropolis.

The water of the Lee they found naturally not only wholesome, but comparing favourably with that supplied to other places. They agreed with the Rivers Commission that it was liable to serious contamination, but they suggested certain alterations in the remedial measures proposed, and expressed their opinion that when these were carried out the water supplied by the companies would be of unquestionable character.

They also approved the North Kent water, and considered this company had an adequate command of quantity for many years to come.

They went elaborately into the question of constant supply, and recommended that it should be enforced, under strict provisions to prevent waste, and to ensure the suitable condition of all the house fittings.

They finally recommended that the duty of seeing that the water companies properly fulfilled their obligations should be imposed on the Metropolitan Board of Works; and that a new Act should be passed consolidating all the laws at present in force as to the metropolitan supply, and introducing the new measures they had proposed.

129. In 1868 an Act (31 & 32 Vict. cap. 154) was passed to make better provision for the preservation and improvement of the River Lee and its tributaries. It was analogous to the Thames Conservancy Act of 1866, altering the constitution of the managing body, and rendering illegal the admission of sewage or offensive matter into the river, except in the case of certain towns where measures had been adopted for its purification.

PART IV.

ON THE SUPPLY OF WATER AVAILABLE FROM THE BASIN OF THE THAMES.

130. We have now to consider the eligibility, for the future service of the metropolis, of the great source from whence its supplies have hitherto been drawn, namely, the basin of the River Thames.

The gigantic schemes proposed for supplying London with water gathered in the distant mountain ranges of the country have been projected on the assumption that the nearer and more natural supply derived from the Thames valley was either deficient in quantity or unsuitable in quality, or both. It becomes, therefore, our duty to inquire whether there is sufficient justification for either of these suppositions; and we will consider them each in turn.

Section I.

AS TO QUANTITY.

131. At the end of Part II. of this Report we have endeavoured to give a general view, scientifically considered, of the most important natural features of this great basin, having reference particularly to its underground storage, and the nature and distribution of its springs. It will be here our object more practically to consider the evidence as to the quantity of water actually obtainable from the rivers and wells in this district.

On this point we have received a large amount of information from a great number of witnesses, who, from their position, experience, and knowledge, are most competent to judge of the subject.

132. The portion of the basin first to be considered is that above Hampton and Ditton, where the water companies have their intake. This portion extends over a length and breadth of 80 or 90 miles, its superficial area being given as 3,676 square miles.

The Thames first assumes importance near the small town of Lechlade in Wilts, where a number of small streams, forming the head waters of the river, unite. From this point down to Ditton it follows a tortuous course of about 120 miles in length, and is joined on either bank by several important tributaries.

133. The rainfall in the Thames basin has been determined with considerable accuracy by many years' observations by numerous persons at various localities from London to Cirencester. It is found to vary, on an average, from about 25 inches at the former place to 30 inches at the latter. Taking the mean of the whole area, Mr. J. T. Harrison estimates the average rainfall to be 27¾ inches, and of this it is estimated that one-third flows down the Thames. 4671. 6838. 2966. 3036.

134. It is desirable, however, to investigate the volume of the stream more particularly; taking our data at the point most important for our purpose, namely, at the intake of the companies, a little above the highest point reached by the tide, and where the natural fresh water stream has its maximum volume.

It has been shown that the total discharge at Kingston for eleven years was 5,432,418 millions of gallons, which is equal to an average of about 1,350 millions of gallons per day, or equivalent to about nine inches of rainfall. If this were the constant flow, no question could arise as to its sufficiency; but we need hardly say that it varies very widely at different times. In floods the stream is so large as scarcely to admit of accurate measurement; but in dry seasons it is much reduced; and it is in reference to the volume in these seasons that the doubt has arisen. It is therefore to this that we must direct attention. 3904.

135. Several witnesses have spoken to this point; we may first give Mr. Bateman's views as to the supposed deficiency in quantity, which has been one ground why he has considered the Thames ineligible, and has proposed to go to the mountains of Wales. He says:

App. E. "When the Acts of 1852 were passed it was estimated that the minimum quantity of water at Hampton was 362,000,000 gallons per day, and this minimum has been habitually considered, in round numbers, as 400,000,000. During the month of September in this year (1865) the river has been carefully measured above the waterworks at Hampton, and the gross daily quantity for a considerable period together has scarcely exceeded 300,000,000 gallons."

6515*a*–6522. 6540–54. In subsequent evidence he explains that the actual quantity given by his gaugings at Hampton in 1865 was 308,720,000 gallons per day, and he describes fully the mode in which the measurements were taken.

4561–4651. 136. Other witnesses give larger amounts. Mr. Simpson states that he has gauged the quantity flowing down at Kingston daily since 1852, and found the minimum in 1864, the driest year known, was 380,000,000 gallons per day, after the whole of the companies had taken their supply. He adds that this was in extreme drought, the usual flow in dry seasons being seldom lower than 600 to 700 millions of gallons.

3266. Mr. Beardmore states that the mean flow at Kingston in the months of June, July, August, and September, for 1864 and 1865, the two driest years, was between 380 and 390 millions, including the companies' supplies, and the absolute minimum only a little lower.

2931 *et seq.* Mr. John Thornhill Harrison, C.E., member of the Royal Commission on the Pollution of Rivers, (who specially investigated the subject, and during their inquiry received much information on the capacity of the basin for affording a water supply,) has put in an extensive series of tables illustrating the meteorology and hydrology of the Thames basin. Confining our attention to those portions of the tables which illustrate the state of the water in the driest seasons, we find that he has given particulars of the actual discharge in the three years 1858, 1859, and 1864, at the times when the quantity was under 400,000,000 gallons per day, and he shows the number of days in each year when the volume attained certain amounts.

The quantity was below 400,000,000 gallons

In 1858 for 36 days.
„ 1859 „ 32 „
„ 1864 „ 8 „

The lowest quantity noted was 350,000,000 gallons per day, and this was observed

In 1858 for 20 days.
„ 1859 „ 14 „
„ 1864 „ 2 „

4259. Mr. Leach, the engineer to the Thames Conservancy Board, says that having often gauged the river at Teddington, he has never found it less than 380,000,000 gallons per day.

6005–8. Mr. Quick, engineer to the Grand Junction and the Southwark and Vauxhall Companies, says the lowest gauging that has ever been taken of the Thames has amounted to 360,000,000 gallons at Teddington.

All these quantities, except Mr. Bateman's, are below the intake of the water companies, and therefore are exclusive of the quantity abstracted by them, which is at present about 50,000,000 gallons per day.

137. We think from this evidence we may fairly conclude that a daily flow of 350,000,000 gallons per day is a very exceptional thing, occurring only for a few days in the course of many years.

138. The companies are empowered, under their present Acts and agreements, to take as follows:—

	Gallons per day.
Chelsea Company	20,000,000
West Middlesex	20,000,000
Grand Junction	20,000,000
Southwark and Vauxhall	20,000,000
Lambeth	20,000,000
East London	10,000,000
Total	110,000,000

139. We are led to believe that it would be easy to make storage reservoirs and other works on the upper part of the river to collect the flood waters; and that by means of these the flow might be so equalized as to neutralize the effect of the severe droughts, and therefore to admit of a still larger abstraction of water if the growing requirements of the metropolis should render it necessary.

140. We will give a summary of the evidence we have received as to the quantity obtainable from the river.

Mr. Hawksley considers there is capacity in the Thames watershed to supply a sufficient quantity for the metropolis. The companies might take the maximum supply they are entitled to without injury to the river, or interference with the navigation. Below Teddington the river is tidal, and the abstraction of water would not interfere at all with the scour; for this reason, that the upland water of the Thames in its ordinary state has little or no influence upon it. It is chiefly when in flood that it has an influence on the scour, and the floods of the Thames are so enormous that practically the quantity taken by the water companies then disappears from the calculation altogether. The maximum flood in the Thames is about 20,000 to 25,000 millions of gallons per day. He considers that a quantity nearly double the statutory limit might be taken from the Thames without any storing process; half the lowest volume of the Thames (which he calculates at 360,000,000 gallons) might be taken, and he does not believe it would have any sensible influence. 5055–70. 5106–7.

He believes the average flow of the Thames in three consecutive dry years to be about six inches of rainfall, which would give nearly 900,000,000 gallons per day.

If more was wanted than could be taken at present it might be obtained by impounding the flood waters, and there would be no difficulty in finding sites for reservoirs. 5071–3. 5094.

Mr. Simpson is of opinion that, by proper arrangements, the Thames basin is capable of supplying 200,000,000 gallons per day. There is no necessity for making reservoirs at present; there is plenty of water. The supply might be increased considerably, and afterwards might be supplemented by reservoirs to double the amount. But it may be fourteen or fifteen years before such works become necessary. 4572–6. 4596. 4646–7.

He assumes that 200,000,000 gallons could be obtained from the Thames, and 60,000,000 gallons from the Lee, which would, at 30 gallons a head, be sufficient for a population of 8,700,000, and that practically, therefore, the Thames may be looked forward to as able to supply London beyond any probable increase. 4721–2.

Mr. Simpson says, that supposing it desirable that large works should be made in the Thames valley to admit of the supply being increased to four times its present amount, the various companies to be benefited should contribute to the cost of such works, but that their execution and maintenance should be left in public hands. 4587-93.

Mr. Beardmore agrees that by the provision of storage reservoirs for the flood waters it is quite practicable to take a much larger quantity from the Thames than at present, not only without any injury to the river below Teddington, but with very great advantage. He considers that from the Thames and Lee together 300,000,000 gallons may be obtained. 3321. 3328.

Mr. J. T. Harrison is of opinion that reservoirs might be made, in the upper districts of the Thames, sufficient to provide for a very large deficiency in droughty seasons. 3092–100.

The Rev. Mr. Clutterbuck, and Mr. Bailey Denton, whose plans and suggestions we have noticed in Part II., agree in the opinion of the sufficiency of the Thames for any probable requirements for the supply of London, if proper provisions were made for storage. 1839. 1532.

Mr. Rawlinson expresses his opinion that a supply may be obtained from the Thames sufficient for London, both present and future. 1360.

Mr. McClean (whose plan for bringing water from Henley has been noticed in Part II.) is of opinion that by storing the flood waters in the upper reaches of the Thames more water may be obtained than can ever be required. He quotes as follows from a Report on the Thames by the late Mr. Blackwell, who was for many years engineer of the Kennet and Avon Canal:— 3637. 5498 *et seq.*

"In a geological point of view the River Thames is, of all the large rivers in England, that in which we may expect the slowest and most constant influence of the rain that falls. From the basins of its tributaries, the rivers Kennet and Loddon especially, consisting as they do almost entirely of chalk or other pervious subsoil, the water finds its way very slowly; and it is not until after many weeks of drought that any diminution of the quantity they supply is perceived.

"The results of my own carefully repeated experiments quite agree with the conclusions that a scientific consideration of the above data would lead to. The volumes of the Thames at Henley, as well as those of the

Kennet and the Loddon, have been repeatedly gauged, and the results obtained lead me to the conclusion that at the time of the shortest water the quantity passing the point at which we propose to take our supply is not less than 55,500,000 cubic feet, or 345,000,000 gallons daily. This is the minimum of the gaugings, and taken near the termination of an unusually long protracted season of drought."

5746-59. Mr. Thorpe, the acting chairman of the Thames Conservancy Board, is of opinion that the whole quantity of 100,000,000 gallons per day, which the companies are empowered to take, might be abstracted without any evil effects on the river as a navigable stream, and that if certain alterations were made, and certain works executed for storage, the quantity might be exceeded.

3601-13. Captain Burstal, secretary to the same board, considers that an enormous quantity more than is drawn already may be drawn above Teddington lock, without the river feeling it to any great extent. He considers reservoirs might be made above Oxford for this purpose with facility and advantage.

4244 *et seq.* Mr. Leach, engineer to the same board, has never observed any evil effects on the scour from the abstraction of water, nor does he apprehend any, supposing the companies to draw to their full authorized extent. For the greater part of the year the largest abstraction they could make could not be detected in the volume of the river. He thinks the Thames basin and the Thames stream are equal to the growing requirements of the metropolis without injuring the scour.

4300-14. He considers storage reservoirs would be desirable auxiliaries; they would equalize the flow, but still would give sufficient flood action for scouring purposes. There is a district above Oxford well calculated for the formation of reservoirs. The companies might take more than 100,000,000 gallons without reservoirs. With storage reservoirs he thinks 200,000,000 gallons might be taken per day and the river still maintained in a perfect state.

In reference to complaints which are stated to have been made as to the effect of abstracting the water on the upper part of the tideway, he says:—

"I think that more complaint has been made from persons residing in that part than any other of the ill effects which have been presumed to follow the abstraction of the water. In my opinion they have been quite mistaken upon that, they have attributed to the abstraction of the water from the river that which has arisen from an entirely different cause. The fact is that the Thames in the tideway for the last 30 years or more has been undergoing very great changes. The bed of the river in and about London has been depressed by the excavations which have been made in it, but at the upper extremity of the tideway it has remained pretty nearly the same. The consequence is that the inclination from that point down to where the excavations have taken place has become much greater, and consequently the stream is much more rapid, and therefore instead of the normal flow of the river passing off gradually as it did formerly, it now runs off very quickly, producing a much sharper stream in the upper part of the tideway towards the time of low water than there used to be, and whatever supply there is of water is consequently carried off more rapidly."

6005-8. Mr. Quick thinks there is no doubt that the basin of the Thames would be able to supply a larger quantity than the companies have power to take. If it were necessary storage reservoirs might be provided in the upper Thames; but as the companies only take now one-seventh of the minimum flow, it would be a long time before anything of that kind would be required.

It will be seen by the above extracts that there is a general accordance among the witnesses as to the sufficiency of the Thames. Mr. Greaves, however, the engineer of the East London Waterworks, says,—

5182-9. "I do not think these rivers are going to last as long as Mr. Hawksley does; I think it is necessary to be cautious in time; I would not like speculating upon any one of those rivers round London lasting for the next half century; not only the Lee or the Thames, but other rivers; I mean lasting as a source of water supply independent of any foreign aid. I think it is quite a fair thing in prospect to talk about going beyond the Thames basin; that is to say, you will either have to do that or to store very largely, more largely than anyone has entered into the practical estimation of."

At the same time Mr. Greaves adds that he does not think the time is yet come for going beyond the Thames; and when further examined as to his reasons for doubting the capacity of the river, he appears to base them on the assumption of a possible change of climate as affecting the flow.

It is to be regretted that there is almost an entire absence of reliable information as to the flow of the river except at one point. It would be very desirable to establish a series of gaugings of the Thames at various points of its course, and of its chief tributaries, showing the variations at different times.

141. Considering the whole of the evidence above referred to, we believe we are justified in inferring, in the first place, that the quantity at present authorized, namely, 110,000,000 gallons per day, might safely be drawn from the main stream of the Thames in its present state; and, secondly, that by means of proper works for storage this quantity might be doubled if required.

Subsidiary Basin of the Lee.

142. But apart from the main stream of the Thames it is also necessary to inquire into the additional quantity which may be obained from the subsidiary basin of the River Lee. Full information as to this basin is contained in the Report of the Rivers Commission. Its area is about 500 square miles; and the mean rainfall, which is equally well determined with that of the Thames, is given by Mr. Beardmore, the engineer of the river, at about 25½ inches. The upper part, above Hertford, is entirely chalk, the lower part almost entirely London clay.

The two companies who draw water from the river appear to have the right of appropriating the whole flow, with the exception of a quantity of about five millions of gallons per day reserved for lockage on the navigation. The actual mean quantities at present drawn by the companies from the river are:—By the New River 18 millions of gallons per day, taken at the upper part of the river, between Hertford and Ware (this being part of their whole supply of 23¾ millions):—by the East London Company 19¼ millions of gallons, taken lower down:—making on the whole 37¼ millions of gallons per day on the average of the year, the quantity in the summer months being increased to about 40 millions. Adding to this the lockage, it gives a total present demand on the river in the summer of about 45 millions. 3961.

We may now compare this with the quantity naturally flowing down the river.

Mr. Beardmore has given us tables of the flow of water in the Lee for 19 years. He makes the average daily flow at Feilde's weir over this time 108·8 millions of gallons; and in the months of June, July, August, and September, of five dry years, he makes it (including the companies' supplies) average 45·2 millions, which is increased by springs in the valley below the weir. 7444.

It is therefore clear that in dry seasons little or no increase is to be relied on from the river in its present state; the only question is, to what extent might the dry weather flow be augmented by storage reservoirs.

143. The evidence on this point is as follows:—

Mr. Beardmore believes that reservoirs may be made within practicable and reasonable limits of expense, so as to store the winter flood waters, and deliver about 70 to 90 millions of gallons daily. 3313–4. 3438–9.

Mr. Muir, the engineer of the New River Company, states that the company calculate that by making such reservoirs they might obtain an additional 10 million gallons; and he believes the East London Company might do the same. 3972–80. 4020–1.

Mr. Greaves, engineer to the East London Waterworks, says that at one time in 1864 they took the whole volume of the river, after the New River had served themselves; there was nothing went by: they are now increasing their reservoir room to store partially the flood waters, which would give, say, five millions of gallons extra over 100 days' drought. He adds, however— 5131–9.

"I am of opinion that as the larger portion of London is dependent upon the Lee, it ought not to continue any longer dependent upon the Lee alone for its supply of water as to quantity. The caution that we had from the drought of 1864 was convincing. There is no room to doubt the question any longer." 5177.

Mr. Greaves's attention being directed to the propositions of the New River engineer above quoted, he says:

"I am not inclined to store so largely, or to depend upon storage to that extent, because I know that there are winters when it is quite likely those reservoirs might not be filled; the winter of 1858 went off without a single flood; we have charge of the floodgates ourselves on the river at Lee Bridge, which govern the whole flow, and in the winter of 1858 we did not draw a single gate; therefore where would the reservoirs be filled from in such a season? I consider the Lee alone not to be depended on, even for the East of London, and less so supposing the New River Company do an equal amount of work." 5178–9.

Mr. Mylne, whose plans for increase of the supply from the basin of the Lee we have noticed in Part II., conceives that by these plans the quantity derivable from this source might be raised by storage to 70,000,000.

The Rivers Pollution Commission, in their Report on the River Lee, 1867, say:

"With regard to the capability of the River Lee to meet the increasing demand for water supply in the eastern districts of London, it may be taken that no dependence can be placed upon an increase of the supply from the river without the construction of impounding reservoirs on a much larger scale than those now in existence."

144. We believe that we ought not to calculate on any material increase from this source, and that we may consider the quantity which the Lee valley can contribute to the supply of London as not more than 50 millions of gallons daily.

Subsidiary Supply from the Chalk.

145. We have referred fully in Part II. to the great store of water contained in the chalk round London.

6141. The only use now made of this for the metropolitan supply is by the Kent Company; who draw at present from it above seven millions of gallons daily, and appear to rely on an almost unlimited power of increase.

Many witnesses before us have testified in favour of this source, and the suggestions of Mr. Clutterbuck, Mr. Homersham, Mr. Barlow, and Mr. Meesom for utilizing it will be found noticed in Part II.

2520. Mr. Hawksley says that there are large districts of chalk where an immense quantity of
5083. water might be obtained, and that there is very fine water surrounding London in all directions, which only wants utilizing.

4045. Mr. Muir also speaks of the ease with which water is obtained in the chalk, and the abundant supply.

146. We do not agree with those who expect to get an almost unlimited increase of quantity of water by simply tapping the natural reservoirs in the chalk, for the supply to them must obviously be limited by the amount of rainfall. Moreover, as the water which penetrates into the reservoirs, raising the water line more or less above the level of the adjoining valleys, ultimately in greater part finds its way by springs into streams at the lower level of the district, any water drawn from the store by artificial means will most probably be at the expense of those streams.

If this be true, it follows that any water obtained by tapping the chalk reservoirs that feed either the River Lee or the Thames above Hampton, would only *pro tanto* diminish these streams, and would therefore be little or nothing gained to the general supply.

147. But there is, in the large area of chalk to the south and south-east of London, a reservoir which does not feed either of these streams, as its surplus waters find their way by innumerable springs into the Thames below London. From this reservoir, in all probability, large quantities might be drawn, and these quantities would be real additions to the supply.

We have no complete data as to the quantities which could be so obtained; but looking to the facts that the present few wells of the Kent Company are supplying above seven millions of gallons, and are said to be capable of supplying twice as much; that the Grays springs are said to be capable of supplying 10 millions; and that a small district near Gravesend has furnished an equal quantity; we believe we are very moderate in estimating the addition that might be made from this source by proper works at 30,000,000 gallons per day.

It is further probable that a considerable quantity of water, soft and of good quality, might be obtained in the neighbourhood of London by means of artesian wells in the *Lower Greensands;* but of this quantity there is no means of forming an estimate without further investigation.

Summary.

148. Combining now these several sources, we may estimate that if ever the metropolis should increase to such an extent as to render necessary such a large supply, and to justify the outlay for works necessary to obtain it, we may calculate on getting, from the basin of the Thames—

	Gallons per day.
From the main stream, supplemented by the aid of store reservoirs, say - - - - - -	220,000,000
From the Lee - - - - - - -	50,000,000
From the chalk to the south and south-east of London - -	30,000,000
or say, a total of - - - - -	300,000,000

Section II.

AS TO QUALITY.

149. We now proceed to consider the part of our subject which is probably the most important as well as the most difficult of the whole, namely, the *quality* of the water obtained or obtainable from the basin of the Thames.

The importance of this point is indisputable. It admits of no question that the metropolis ought to be supplied with water that is perfectly wholesome in quality. Water is a necessary of life; the consumers in a place like London have no power to choose their own source, but are at the mercy of the parties undertaking the supply; the health, often even the life, of the inhabitants is in the hands of these parties, and it is therefore a matter of paramount public interest that the manner in which they exercise this immense power should be jealously watched, and efficiently controlled. And if it could be clearly proved that either now, or in a proximate future, wholesome water could not be obtained from the Thames basin, the question of the abandonment of the source would demand prompt attention.

We have alluded to the difficulty of this question, because we have found not only that opinions are divided upon it, but that the elements which enter into its determination are of a very subtle character, and by no means admit of the satisfactory kind of treatment which we are in the habit of expecting from the modern advanced state of physical science. We have endeavoured to get the best information possible, from scientific men of the highest reputation, and who have had the best means of making themselves acquainted with the subject, and we have given their evidence its due weight; but we have also been obliged on some points to rely on other considerations in arriving at our decision.

150. It is nearly half a century ago that attention was first directed to the quality of the water supplied to London, and the Royal Commission of 1828, appointed in consequence of complaints on this head, reported to the effect that the water was naturally good, but was fouled by the admixture of foreign matters; and this led to the introduction of filtration, by which the quality was much improved.

The Board of Health report of 1850 pointed out the impure state of the Thames within the tideway, but objected generally to the Thames water, even in its purest state. The Chemical Commission of 1851 reported fully on the subject, in terms we shall have to quote hereafter; and in 1852 a great improvement was effected by the passing of the Metropolis Water Act, which compelled the companies to take their water from a point above the tideway, to filter it effectually, and to preserve it in covered reservoirs.

In 1866 and 1868, in consequence of the reports of the Royal Commission on the Pollution of Rivers, Acts were passed compelling towns and villages within certain limits to dispose of their sewage without polluting the Thames and the Lee; but the effects of these Acts have not yet been proved.

151. We may most conveniently divide this part of our inquiry into two heads:—

A. What is the evidence as to the present quality of the water in the Thames and its tributaries?

B. What are the influences likely to affect its quality for the future?

A.—ON THE PRESENT QUALITY OF THE WATER IN THE THAMES AND ITS TRIBUTARIES.

152. We have taken a large amount of evidence, tending to illustrate this question, from persons of the highest authority, and whose opinions on the various points involved in the inquiry we shall quote in their proper places. But as, on several previous occasions, the waters of the Thames have been analysed and reported on, we have deemed it right also to refer to such of these analyses as appear to us most authoritative and trustworthy. And we may mention the following as deserving of special attention:—

The Chemical Commission of 1851 gave a full analysis of the waters then supplied to London, which we have reprinted in Appendix A F.

In 1856, after the water companies had removed their sources of supply from the Thames to points above the tideway, in accordance with the Act of 1852, a further analysis was made on behalf of the Government, by Messrs. Hofmann and Blyth. We have reprinted portions of this analysis in Appendix B G.

On the inquiry by the House of Commons Committee in 1867, analyses were put in evidence, made by Dr. Letheby, Dr. Odling, and Professor Abel; these we have reprinted in Appendix A G.

The same chemists have also made for the London water companies a later analysis, which has been sent to us, and which we have printed in Appendix A H.

Another set of analyses that deserve special attention are those published monthly by the Registrar General. It appears that after the cholera epidemics of 1849 and 1854 the attention of this department was drawn to the water supply of the metropolis, and an arrangement was instituted by which a monthly analysis of the waters was made, in the first instance by Dr. Robert Dundas Thompson, then by Professor Hofmann, and latterly by Dr. Frankland. The results are published once a month in the Registrar General's returns of the health of the metropolis, and a summary is made at the end of each year. We give some examples of these documents in Appendix A J.

153. The analyses above referred to all apply to waters actually delivered in London by the various companies, and taken from their ordinary sources of supply; but we found that the extended nature of our inquiry rendered these data insufficient. It was our business to report on the water of the Thames basin generally, and therefore it was necessary that our information should not be limited to one point, but that we should know something of the general quality of the water in different parts of the basin, and should endeavour in the first place to ascertain its natural condition when in its pristine state of purity, and then to trace, as far as we could, the various influences it was subject to during its flow. For this purpose, with the sanction of Your Majesty's Treasury, we determined to have samples of water collected from various parts of the basin and analysed in the same manner as in the cases of the Welsh and Cumberland districts. The selection of the samples was entrusted, as before, to Mr. Pole, whose report thereon will be found in Appendix O, and the analyses of the waters by Drs. Frankland and Odling are given in Appendices A X, 1 and 2.

154. We shall, in treating of the chemical quality of the waters, adopt the usual plan of making a broad distinction between the *mineral or inorganic contents*, such as metallic and earthy salts, which in the case of river waters are found present in their first sources; and the *organic contents*, which become added to the waters by accidental circumstances during their flow.

155. The mineral or inorganic contents of the Thames water supplied by the companies from Hampton appear to amount usually to from 15 to 20 grains per imperial gallon of water, of which more than one half is carbonate of lime, and the rest sulphate of lime with salts of magnesia, soda, potash, and silica, and traces of alumina and iron.

The waters of the Lee valley, as supplied by the New River and East London companies, differ little from those of the Thames; but those of the Kent Company being drawn directly from the chalk, contain a considerably larger quantity of the salts of lime.

156. The point, connected with these mineral contents, which is of the main importance in our present inquiry, is their influence (chiefly caused by the presence of lime) in giving to the water the peculiar quality called *hardness*. In the investigations that have taken place from time to time on the water supply of the metropolis, the hardness of the water has always been a prominent topic of discussion, often involving elaborate general comparisons between the eligibility of hard and soft water respectively for the supply of towns. It is, therefore, necessary that we should give a summary of the information we have obtained on this point, and the conclusions at which we have arrived thereon.

On the Hardness of the Thames Water.

157. Owing to the solvent power of water, all waters percolating through or flowing on the surface of the earth take up more or less mineral matter, consisting in almost all cases of carbonate of lime as the essential ingredient, and of a few other salts as subordinate ones. When these mineral matters are in excess the waters are called mineral waters; but in moderation, say 15 to 30 grains to the gallon of 70,000 grains, they are present in almost all river waters.

Water charged with salts of lime has the property of decomposing soap to a certain extent, by the combination of the lime with the alkali, and this is what is meant by the popular description of the water being "hard." Soft water makes a lather freely, but

hard water curdles a portion of the soap, and requires consequently more of it for the purpose of washing.

158. The first attempt to investigate the hardness of water in a way combining scientific research with practical utility, was by the late Dr. Clark of Aberdeen, who shortly before his death wrote to our chairman the letter on the subject which we have printed in Appendix G. His attention was directed about thirty years ago to the hardness of the London waters, and in March 1840 he took out a patent for a mode of softening them. This invention has proved to be a practicable process of much utility, and we shall have occasion to refer to it hereafter; it is important to our present object that in his patent Dr. Clark described a mode by which the hardness of water could be *defined* with great exactness. He first formed a series of artificial waters of several grades of hardness, each containing a known proportion of bicarbonate of lime; and when any unknown water was to be tried he compared its effect on soap, by an ingenious process, with these as standards, and so at once obtained an accurate measure of its hardness. He proposed to designate the hardness of water by the *number of grains of bicarbonate of lime contained in one imperial gallon* (or 70,000 grains) of a standard water producing the same curdling effect. This process is known as "Dr. Clark's test," the number of grains being called "degrees." It is exceedingly easy of application, even by persons without any chemical experience; it is very definite and accurate; and it has been very generally approved and adopted by chemists treating of the subject. The Registrar General's reports, however, give the number of grains of carbonate of lime in 100,000 grains instead of 70,000, so that to compare these degrees of hardness with those usually adopted, they must be reduced in the ratio of 10 to 7.

159. The water of the River Thames, supplied as it is in great part by springs from chalk and oolitic limestone, is naturally somewhat hard. It is, however, well known that flowing water tends to part with a portion of the carbonate of lime it holds in solution, and therefore, whatever may be the hardness of the water as it issues from the chalk or any calcareous strata, after a flow of some miles it falls to a nearly uniform standard, varying from about 12 to 15 degrees in the imperial gallon.

The Chemical Commission of 1851 gave the hardness of the metropolitan waters as follows:—

"The hardness was remarkably uniform in the water of the eight principal metropolitan water companies.

"The degrees of hardness, by Clark's soap test, of the waters of the eight principal London companies, observed on the 29th, 30th, and 31st of January, were as follows:—

"From other sources than the Thames.	New River	14°·9
	East London	15°·0
	Kent*	16°·0
"From the Thames.	Grand Junction	14°·0
	West Middlesex	14°·6
	Vauxhall and Southwark	15°·0
	Chelsea	14°·4
	Lambeth	14°·2
	Lambeth (from Thames Ditton, March 8)	14°·2

"The variation observed in this property is from 14° to 16°; or if the Kent water be excepted, from 14° to 15°, or one degree only. It appears also, from observations made at different seasons, that this range is not considerably exceeded at any period of the year, except during floods, when the hardness of Thames water may fall to eight or nine degrees."

The analyses by Drs. Letheby, Odling, and Abel of waters taken between December 1866 and February 1867 give the hardness from 13 to 14½ degrees; that of waters taken in May, June, and July 1868 is somewhat less. They say,— App. A G. App. A H.

"On reference to Table No. 1, it will be observed that the hardness of the water supplied by the Thames companies ranges from 11·3° to 12·5°—that from the New River being 11·9°; while the water from the East London Company has a hardness of 11·7°; and that of the Kent Company a hardness of 17·6°.

"After boiling for fifteen minutes, the hardness of the water from the Thames companies is reduced to between 2·4° and 3·5°; the New River water to 2·3°; the East London water to 2·6°; and the Kent Company's water to 6°.

"On comparing these results with the return of analyses made by us in the winter of 1866–7 (in reference to the Metropolis Water Inquiry, conducted by a Committee of the House of Commons in 1867), it will be observed that in all instances excepting that of the Kent Company's water (derived solely from deep wells), the hardness is less than that of the water collected during the winter season, a result which is in accordance with previous experience regarding the fluctuations in the composition of river water at different seasons."

The analyses of the Registrar General, when corrected on account of their unusual form, give a variation in 1847 from 11¼ to 16 degrees, omitting the Kent water, which varied from about 15 to 20 degrees.

* At this time the Kent Company took water from the river Ravensbourne.

App. A X. The analyses made for ourselves by Drs. Frankland and Odling show the following results when reduced to Dr. Clark's scale:—

	Hardness according to Dr. Clark's scale.	
	Before boiling.	After boiling.
Head Waters.		
Oolite Springs	15·3	3·4
Main Stream of the Thames.		
At Lechlade	15·3	3·6
Above Oxford	12·7	5·4
A little below Oxford	13·4	5·7
Seven miles below Oxford	15·4	6·3
Above Reading	14·7	5·7
A little below Reading	12·7	4·0
Five miles below Reading	14·0	5·3
At Medmenham	13·6	5·3
Above Windsor	15·5	5·2
Below Windsor sewer	15·7	5·2
Three miles below Windsor	14·6	7·4
At Hampton	14·0	3·0
Tributaries.		
Cherwell	15·9	3·6
Thame	17·9	4·5
Chalk Spring, Watford	17·3	2·6
Kennet above Hungerford	15·2	2·5
„ „ Reading	13·7	1·7
Bagshot Sands	1·0	1·0
Wey	5·8	5·6
Mole	11·3	3·1
Outlying Waters.		
Lee and Mimram mixed	14·0	1·5
Amwell Well	14·7	4·1
Caterham Well	16·4	6·3
Croydon Well	15·4	6·4
Wandle at Mitcham	14·8	6·8

160. The hardness of the London water does not seem prominently to have attracted attention, as forming any serious objection to the source, till the appearance of the Board of Health Report of 1850. Indeed, on the contrary, the more general desire seems to have been, when the Thames was found fault with, to resort to the chalk springs, whose water was harder still. The Board of Health, however, were of a different opinion, and laid so much stress on the supposed evils of the hardness of the water as to recommend the abandonment of the Thames almost on this ground alone.

161. The effects of hardness have been discussed in regard to the use of the water—

a. For drinking.
b. For culinary use.
c. For washing and for manufacturing purposes.

We propose to give a summary of the evidence we have been able to collect on each of these points: but before doing this we may quote a few explanatory observations, by the Chemical Committee of 1851, who devoted much attention to this branch of the subject, and to whose opinions on it we attach great value.

162. They say—

"It may be useful to distinguish the quality known as the 'hardness' of water according as it is of a temporary or permanent character. Perfectly pure or soft water, when exposed to contact with chalk (carbonate of lime) is capable of dissolving only a very minute quantity of that substance; one gallon of water, in weight equal to 70,000 grains, taking up no more than two grains of carbonate of lime. This earthy impregnation is said to give the water two degrees of hardness. But waters are often found containing a much larger quantity of carbonate of lime, such as 12, 16, or even 20 grains and upwards in the gallon. In such cases the true solvent of the carbonate of lime, or at least of the excess above two grains, is carbonic acid gas, which is found to some extent in all natural waters. But this gas may be driven off by boiling the water, and the whole carbonate of lime then precipitates in consequence, or falls out of the water, with the

exception of the two grains which are held in solution by the water itself. The gas-dissolved carbonate of lime gives therefore temporary hardness curable by boiling the water. An artificially prepared hard water, containing 13½ grains of carbonate of lime to the gallon, was observed to decrease from 13·5 to 11·2 degrees of hardness, merely by heating it in a kettle to the boiling point. Boiling for five minutes reduced the hardness to 6·3 degrees, 15 minutes to 4·4 degrees, 30 minutes to 2·6 degrees, and one hour to 2·4 degrees. The softening effect of boiling does not therefore appear all at once, but the greatest proportional effect is certainly produced by the first five minutes' boiling. The West Middlesex and New River waters were both found to soften by boiling, very much in the same manner as the preceding pure chalk water, except that the ultimate hardness of the two waters specified was somewhat higher. By an hour's boiling the West Middlesex fell from 14·6 to 5·5 degrees, and the New River from 14·7 to 4·1 degrees.

"Other salts of lime, such as sulphate of lime, are generally dissolved in water without the intervention of carbonic acid gas, and therefore remain in solution although the water is boiled, imparting hardness.

"The carbonate of lime in water decomposes about 10 times its weight of soap in washing (more exactly 8·8 white curd soap and 10·7 common yellow soap), and other salts of lime act injuriously upon soap, in proportion to the lime they contain; the soluble soap containing soda being converted into an insoluble and useless compound containing lime. The water is then deprived of lime or softened at the expense of the soap. The lime in 100 gallons of Thames or of New River water thus occasions the destruction of about 34 ounces of soap, before any portion of it becomes available as a detergent."

a. Effects of Hardness of Water for Drinking Purposes.

163. The Board of Health collected evidence on this point, and expressed an opinion "that the presence of lime and other mineral matter deteriorates the wholesomeness and "value of waters for the purposes of drinking."

The Chemical Commission of 1851 held different views. Their Report says:—

"When in good condition, the Thames water possesses the peculiar and agreeable brightness of chalk waters, arising from the entire absence of colour, combined also usually with good aëration.

"The Thames water may be described to be, in circumstances not unfavourable to purity and coolness, a palatable water. The amount and nature of its saline constituents probably contribute to its general acceptability as a beverage.

"It may be safely stated, that no sufficient grounds exist for believing that the mineral contents of the water supplied to London are injurious to health. No reasonable doubt indeed can be entertained of its salubrity. The shallow well waters of London vary from 32 to 80 degrees of hardness, yet these waters have never been pronounced unwholesome.* An aërated water is manufactured and safely consumed to some extent which contains 92 grains of carbonate of lime to the gallon, instead of 12 or 14 grains, as in Thames water. The portion of lime and magnesian salts in the water drunk must indeed be greatly exceeded in general by the quantity of the same salts which enters the system in solid food. The only observations, from which an interference of the lime in water, in deranging the processes of digestion and assimilation in susceptible constitutions, has been conjecturally inferred, have been made upon waters containing much sulphate of lime and magnesia, as the Brighton shallow well water, or the hard selenitic water of the New Red Sandstone, and have no force as applied to the Thames and its kindred waters, as the earths exist in these principally in the form of carbonate."

164. Mr. Bateman expresses his firm conviction that soft water is very much more wholesome than hard water, but he remarks at some length on the difficulty of finding any tests by which the effects can be truly ascertained. 6680–6700.

Mr. Hawksley says on this point: 2600.

"I imagine there are quite as many fine-raced people living in hard water districts as there are living in soft water districts. I am well acquainted with districts of both characters, and I may say that quite four-fifths of the whole surface of the globe yields hard water—in fact, the cretaceous strata and the other lime formations occupy a large portion, from which alone hard water can be obtained. I think these extend quite to four-fifths of the earth's surface."

Mr. Beardmore states that his experience leads him to consider hard water is preferable for drinking purposes, and Mr. McClean agrees in this opinion. 3381–7. 5641.

Mr. Rawlinson thinks the evidence conflicting as as to what is the best water for health, and believes that change either from hard to soft water, or *vice versâ*, is prejudicial. He considers that by far the greater quantity of water drunk in England is hard water, all above six degrees of hardness being so designated. 1363–80.

Mr. Way thinks the question of hardness would have a reference more to habit than anything else. It is exceedingly doubtful whether water of two or three degrees of hardness is more healthy, because people are in the habit of drinking waters of 17 or 18 degrees of hardness without any apparent injury to health. The waters which are the brightest and most liked are the hard waters—the chalk waters. There is no reason to believe chalk water injurious, except perhaps in some special instances. As to the question of health, he does not attach importance to the hardness, either one way or other, if it is in moderation. 1457–61.

Mr. Duncan mentions the opinion of the medical officer of Liverpool, that a change from hard to soft water was prejudicial. 2185–97.

* The objection more recently brought against the shallow well water in London, is on account of its pollution by the infiltration of organic matters from the soil, and not from the natural mineral contents or hardness.

3934. Dr. Letheby considers a moderately hard water best for drinking purposes and for the general supply of cities. He illustrates this opinion by reference to the supplies of Paris and Vienna. A large proportion of the earth's surface consists of calcareous districts, supplying hard water. He is not aware of any instance of moderately hard water producing gravel or surgical affections.

2646-2719. Dr. Lyon Playfair gives evidence as follows:

As a sanitary question, if the water is otherwise pure, I do not think that mere hardness is of much importance as to health; in extreme cases I would consider a hard water injurious to health, but in ordinary cases, such as the Thames water, I do not think it injurious to health, if there are no other impurities in the water than the mere differences in the amount of carbonate of lime.

In some cases hard water might prove injurious, as in calculous affections and in dyspepsia, still, generally, a tolerably hard water may be taken without much inconvenience; but water of 20 degrees of hardness is very hard water, and I would much prefer, even for purposes of health, that it should be softer.

2661. Taking the water which comes from the springs in the chalk, do you consider that water generally to be prejudicial to health?—No, not prejudicial to health, except in the circumstances which I have mentioned.

2691. Are you aware of any experiments which have been made with regard to the advantages of the use of either hard water or soft water for drinking purposes?—I can only rely upon the experiences of large towns where they have been supplied with hard water and the supply has been suddenly changed to soft water; of course I do not know of the reverse instances where soft water has been suddenly changed to hard, but in the former cases I never saw any deterioration of health.

2692. Do the returns of the mortality of the towns now supplied with soft water show any improvement in consequence of the use of soft water?—I might mention such towns as Liverpool, for instance, where there has been a very large improvement in the health, but the introduction of soft water was only one of many hygienic improvements which took place at the same time; therefore, the proportion which should be attributed to that is difficult to distinguish from the others.

2693. That probably would be the case in almost all instances where a new water supply has been introduced?—It is; for a new and enlarged supply of water generally arises when a population has become awakened to the necessity of hygienic improvements generally.

3124-3218. Dr. Parkes's evidence on this subject is as follows:

With regard to the effect upon health of the use of hard waters, distinguishing between the carbonate of lime water and the sulphate of lime, and sulphate of magnesian waters, the carbonate of lime waters appear in some cases certainly to produce some effect upon health, for instance, dyspepsia, and they do not agree with some class of persons, whereas to others they appear to be quite harmless. There is a large population living upon chalk water, and we cannot trace any very decided effect upon their health in the production of any class of disease—calculus or anything of that kind, but at the same time persons do sometimes suffer from indigestion.

3125. What degree of hardness would, in your judgment, be a safe water, taking an average constitution; some people will live in spite of difficulties; their resistive force being such that nothing seems to affect them, but my question has reference to an average constitution?—I do not think with regard to pure chalk water that there is any evidence that a moderate amount of carbonate of lime in the water does any harm, certainly not on the large scale; in some individuals it produces indigestion.

3126. Would 16 or 20 degrees of hardness be prejudicial?—I think that that degree of hardness would be certainly prejudicial. I think that very probably it might disagree with a great many persons; but supposing it reached to 8 or 10 or 12 degrees of hardness from carbonate of lime, it might be considered probably good water as far as that was concerned, but I should draw a marked distinction between that and the hardness arising from sulphate of lime, or sulphate of magnesia, or chloride of calcium, which would certainly disagree in much smaller quantities, so that the goodness of water for drinking purposes I would estimate according to its permanent hardness rather than according to its temporary hardness.

3134. But supposing the water was equal in purity and free from organic matter, does the question of simple hardness or softness enter into the consideration of those whose special duty it is to care for the troops with regard to the kind of water that they should use?—In all cases we would prefer a soft water if it were possible to obtain it; and if the water were permanently hard, to a large extent that water would be reported upon unfavourably, and better water as regards that property would be procured if it were possible.

3137. Speaking generally, you are of opinion that the mere presence of carbonate of lime of 15 degrees of hardness would not be injurious to health?—With 15 or 16 degrees of carbonate of lime hardness I should say that it would be hard water, and with some persons it would disagree and produce dyspepsia. I think it should not exceed 10 or 12 degrees if possible. At the same time I should wish to state that one would prefer water free from that even, if it were possible to get it.

3201. The greater part of the troops I presume in this country are located in districts where the water is of a moderate degree of hardness; for instance, Dover, Portsmouth, Southampton, Plymouth, and the greater part of Ireland?—Yes, and at Chatham. At Southampton we have no troops, and at Aldershot the troops are upon soft water. At Chichester the water is hard, and at Colchester it is hard. For the most part they are chalk waters.

3202. Have you known instances of any ill effects from the use of such waters?—Not of the good chalk waters.

3203. Have you known any instances where troops have been located in districts where they have been using water of a moderate degree of hardness, and have suffered when they have been removed to a district where the water was soft?—I have never seen any reports of that kind.

3212. Are you aware whether a certain quantity of carbonateof lime may not in many cases be rather beneficial than otherwise to health?—I think that is again very doubtful. The fact is, that almost all kinds of food contain enough lime for the supply of the body, and the quantity of carbonate of lime supplied in water might no doubt be applied to the wants of the system, but I can hardly think that it would be necessary, that is to say, I do not think it should be an argument for the supply of chalk water that lime is thereby supplied.

3217. I see that one disorder which you mention is calculi; have you been able to trace that back to the use of water?—In Germany especially there is a very strong opinion in certain parts that the phosphate of lime calculi and calculi generally are more common in districts where the inhabitants use very hard waters, but in this country the evidence is so far negative; we have not many districts supplied with limestone

waters or the magnesian limestone waters; most of our lime waters are chalk waters, and so far, I think, in this country there is no evidence of there being a greater amount of calculi than in other districts not supplied with this water, but in Germany and, perhaps, in France the evidence is stronger that the use of some of the lime waters may have an influence in the production of some of the calculi.

3218. Would that be in the case of water of an ordinary degree of hardness, or of an excessive degree of hardness arising from the chalk or from the presence of sulphates?—I believe especially from the large amount of hardness arising in most cases from the mixture of chalk and of sulphates, at least it is so in most of those waters.

Mr. Simon says:—

2777–2835.

2777. Has your attention been directed to the quality of the water in London for drinking purposes, as to the effect upon the health of the inhabitants, as compared with water of a softer and purer character?—I have no evidence upon that subject. I think that, practically, the only very important sanitary question as regards the quality of the water supply to London is the question of organic admixture. I do not think that the question of a few grains of lime in a gallon of water can be regarded as a very important sanitary question.

2778. Then, in your judgment, the presence of lime, or two or three degrees of hardness in the water, would not be a matter of much consideration, supposing the water were free from organic impurities?—Quite so, as regards the public health.

2779. For drinking purposes, probably a little hardness in the water would add to its life and pleasantness to the taste?—I would not quite say that; I have found soft waters, or at all events, hard water artificially softened, very agreeable.

As regards drinking purposes, I am not sure of any important difference, but am inclined to prefer the soft water.

2791. Do you know of any experiments which have been made with regard to the use of soft water and hard water upon health?—If by hard water is meant such water as we have in London, I am not aware of any facts of the smallest value showing difference of effect between such water and soft water.

2792. It has been stated that there are certain classes of diseases more prevalent in districts where hard water is used than in others, for example, diseases of the bladder and the stone; can you give us any evidence on that point?—I do not think there is any evidence that is worth a rush upon that subject.

2793. That evidence which was given by Dr. Prout some years ago you do not attach much importance to?—I do not remember the exact language of Dr. Prout upon the subject, nor know whether he professed to argue from any large field of observation; but I believe that no statistics of value exist in proof of such an assertion.

2823. Although it is a hard water, in some cases to even 18 or 20 degrees, yet it would not be in your mind, in a sanitary point of view, objectionable to use that water?—It would not make it unwholesome water, so far as I know, for drinking, but there would remain of course the economical question.

2824. Therefore we may assume that the question, as between the existing water in the Thames basin and pure soft water, would be practically reduced to its economical results for the purposes of washing and culinary purposes and domestic use?—Yes.

2825. As far as the simple sanitary question goes, you see no objection at all to it?—No.

As regards health my bias is in favour of soft water, but I cannot say that I think the case established against hard water (*i.e.*, against hard water of such comparatively few degrees of chalk hardness or carbonate of lime hardness as you have in the London waters) that it acts injuriously on health. It is different, of course, when you come to certain other hardnesses of water; but I do not think that the hardness, for instance, of the New River Company's water can be considered detrimental to health.

Dr. Frankland says:—

6259. 7777. 352–6.

6259. You have spoken as to the properties of the London water with regard to health; what is your opinion as to the effect upon health as between hard water and soft water?—My opinion is that there is no difference.

6277. For drinking water you say you attach no importance to that difference of degree of hardness?—Not as regards its effect upon health, but I attach great importance to it in the use of water for cleansing purposes.

6352. Some difference exists, does there not, in the opinion entertained by medical men and chemists with regard to the effect on health of soft and hard waters?—There has been some difference of opinion on the subject, but I think the general impression now is that there is not much to be said upon that point, that they are equally good as regards their effect upon health.

6355. Have you any reason to suppose that hard water as drinking water might exercise, not any direct influence in the way of supplying carbonate of lime to the body, but in taking away less organic or mineral matter from the body than soft water?—I have never considered the subject from that point of view, I confess; but the quantity of matter dissolved in the hardest water ever used for drinking purposes is such a very small fraction of the total solvent power of the water, that I should not imagine that there could be any substantial difference between the two kinds of water in that respect.

6356. Have there been any experiments upon that point?—No, not that I know of.

Dr. Odling says:—

7054–8.

6439. On the score of health do you make any distinction between soft and hard water?—I do not think there are any facts which enable one to give a positive opinion. Some gentlemen who have considered the subject entertain very strong opinions both ways; but I do not know any facts upon which one can speak positively.

6478. What is your opinion with regard to the presence of carbonate of lime?—For mere drinking purposes I do not consider it a matter of any disadvantage at all.

Sir Benjamin Brodie's evidence is as follows:—

7023. Have you any reason to suppose that the use of soft or hard water as a drinking water produces any difference of effect upon health?—I cannot say I have reason to think so.

7024. Have you any reason to suppose that the health of a district is independent of that?—I have no reason to think it to be dependent upon it.

7025. Is there not a want of direct experiment upon that subject?—Oxford is a place where the spring water is extremely hard, and injuriously hard for every purpose, but I never heard that it had been made out

that Oxford was liable to any particular class of complaint from that reason. If it were so, I think it would have been discovered; but perhaps some physician from the infirmary might tell you to the contrary.

Dr. Miller thinks any precise observations on this point are difficult to obtain, but he thinks, so far as observation goes, it is a matter of indifference whether it is hard or soft water. He adds:—

"It depends upon the quality of the hardness. Chalk waters, I consider, are waters which are perfectly wholesome, but waters which have a similar degree of hardness from sulphate of lime there appears to be some reason to believe are found occasionally to disagree with persons. Still there are waters which are supplied to large populations containing sulphate of lime, and very hard sulphate of lime waters. For instance, the population of Wolverhampton and Birmingham are supplied with water of this kind. It is certainly objectionable, but what I was going to say was that the evidence in that case is that there is no sensible injury to health directly traceable to the water as far as observations go. I believe, generally speaking, the impression is that the hardness caused by sulphates of lime and magnesia is more likely to produce certain slight derangements than the use of chalk waters of a similar degree of hardness. I should not think there was the slightest reason to suppose that any injury would result from such water. From long habit I should certainly prefer hard water for drinking purposes to soft water."

7095. Are not a very large proportion of the waters consumed in this country, or in any other country, flowing as they do over calcareous formations principally, hard waters?—Yes, they are.

7096. And the proportion of soft water used is comparatively small?—The Scotch waters are many of them very soft, and some of the waters in Cumberland are soft. Whitehaven and several large towns are supplied with soft water now, but in the south of the island the water supply is generally hard.

7097. Have you had occasion to notice whether the change from one water to the other produces any ill effects upon the health of the inhabitants?—I have no observations upon that point.

"Have you formed any opinion yourself as to the comparative value of a supply of water of a moderate degree of hardness to a town, or of a soft water supply?—I should say that for drinking purposes a hard water is preferable, and it is liable to a less frequent change than a soft water. The principal objection which appears to me to arise in the case of soft water is that it is liable to peaty discolouration, which makes it at times very disagreeable for drinking purposes, and it is also more liable to absorb organic impurities. I should prefer, merely looking at it as an abstract question, water of a moderate degree of hardness for drinking. I must say that for domestic use soft water is preferable on account of its economy, but for dietetic purposes I think hard water has the preference.

"Do you know of any experiments bearing directly upon that question with regard to the effect upon health?—No, I have no observations upon that point. Having always lived in a hard water district I certainly prefer it for drinking purposes, but I believe persons who live in soft water districts are equally favourable to the use of soft water."

7124. Dr. Angus Smith gives evidence as follows:—

7260. Have you been able to form any opinion as to the effect upon health of the use of soft water or hard water?—I do not think there is good evidence upon that point. I have heard of horses losing their appearance when they used hard water, and of persons of my own acquaintance who got indigestion by coming into hard water districts; but then I must say that those cases are somewhat balanced by people being rather disagreeably affected on going to soft water districts, and especially some of the hilly districts of the north.

7261. That depends a good deal, I presume, upon the previous habits of people?—Yes. I do not think that there is a great deal of evidence on either point. I do not think it is fair, in fact, to take the appearance of the population as any criterion. If we did so, we might find some arguments in favour of soft water. I should think that the tallest people in Great Britain are to be met in soft water districts; for instance, in Cumberland and, probably, in Aberdeen; I may say that the tallest people I have seen in Great Britain are in Aberdeen, which is a very soft water district.

7264. Are not soft water districts generally mountain districts, where they have the purest air as well as pure water?—Yes; I believe, however, it is quite possible for the blood to take up matter which is inorganic dissolved in water.

165. From the above evidence, at any rate, there is no reason whatever to suppose that the hardness of the Thames water would be in the least degree prejudicial to health.

Some eminent chemists have contended that a moderate quantity of carbonate of lime is not only harmless, but that it is actually useful in supplying material for the bones of men and animals. Considering, however, the much larger quantities of carbonate of lime taken in our solid food, such an additional source of supply would seem to be unnecessary. Judging in fact from the condition of the inhabitants of soft water districts well supplied with a variety of food, it is evidently perfectly immaterial, although it may be otherwise in districts short of carbonate of lime, and when the local produce suffers from the same deficiency as the water. Still it remains to be shown whether when large quantities of water are drunk, those waters which contain the smallest quantities of mineral ingredients may not dissolve and take away more from the body than harder waters, and whether there should be any cause for preference on these grounds.

It may also be a question whether, from the better keeping qualities of waters of a moderate degree of hardness, from their general better aëration and greater freshness, and from their lesser solvent power, such waters are not the best for drinking purposes. Perfectly pure water does not exist in nature. All spring and river waters contain more or less mineral ingredients, and it is only in limited mountain districts, where hard and non-calcareous rocks prevail, that water is found approaching a nearer standard of purity. That the use of these purer waters is more conducive to health is without proof; there is,

however, a great want of exact evidence on the subject of the dietetic value of soft and hard waters.

b. For Culinary Purposes.

166. Another of the objections of the Board of Health to the Thames water was that, by reason of its hardness, it was unfit for the preparation of tea, by occasioning waste, and for all culinary processes by diminishing their efficiency and increasing their expense.

167. The Chemical Commission of 1851 remark on this point as follows:—

"The hardness of the metropolitan water supply, which is due to its mineral constituents, may be considered as the same whether derived from the Thames or the Lee, and amounts on an average to about 14 degrees. Although this degree of hardness is considerable and highly objectionable, still it is exceeded by the hardness of pure chalk waters, such as are supplied by water companies to the towns of Gravesend, Dover, and Brighton, and which may be estimated at from 18 to 20 degrees. The deposit which Thames water gives rise to in boilers is also friable and less coherent than the stony deposit from selenitic waters; and means exist, such as the use of sal ammoniac, for entirely preventing the occurrence, in steam boilers, of deposit from chalk but not from selenitic waters.

"The hardness of the London water is also of the least objectionable kind, being chiefly, as has been already stated, temporary hardness, which is removed by boiling. The whole 14 degrees of hardness can be ascribed only to that portion of the water which is used cold. To ascertain the average state of hardness of heated water, portions of water were drawn on six different occasions from the fixed boiler of a kitchen range supplied with New River water; the hardness was found to be 5·4, 4·9, 4·1, 4·1, 4·9, and 5·3 degrees, of which the mean is 4·8 degrees. The hardness of London water, as it is commonly used after boiling, appears, therefore, to be about five degrees, while without heating it amounts to 14 degrees. The distinction between permanent and temporary hardness was illustrated to us at Greenwich, where the brewer described the deep well-water of the Hospital (which is only occasionally pumped up) as a soft water, although its hardness is 21 degrees; but it is only used by him for mashing after being boiled, when, being a pure chalk water, its hardness is reduced to about four degrees. The importance of this distinction was likewise shown, though in another manner, at Whitehaven, where a great and apparently disproportionate advantage has been experienced, from a change in the town supply, from a water which we found to be of 6·7 degrees of hardness to another water of 1·4 degrees. The hardness of the former water, however, although not great in amount, proved to be of the permanent description, as after an hour's boiling the water of the old supply was still of 6·4 degrees, that is, harder than even the Thames water is after boiling. The hardness of the former town supply in Lancashire, although often inconsiderable, was generally of the same permanent character as the old Whitehaven supply.

"The hardness of water forms an objection to its use, both in cooking and washing, but the force of the objection to the Thames water for culinary purposes is much diminished by the large amount to which that water is softened by boiling. Tea is prepared in London with water which, it appears, is practically of only five degrees of hardness. It appears impossible to obtain any standard or test, by which the strength of an infusion of tea can be expressed in numbers, or to find any means of judging of its quality more precise than the indications of taste. On carefully comparing infusions, prepared as for family use, of an equal quantity of tea in the New River water before described, which averaged about five degrees of hardness, and in water of 2·4 degrees only, the observation made on several different occasions was, that the inequality in strength and flavour of the two infusions was altogether insensible to some palates. But an increase in the bitterness was more generally remarked in the soft water infusion, without enhancement of flavour. Where a preference was expressed it was in favour of the quality of the hard water infusion, but the difference between the two infusions was not considered material by anyone.

"Hard water is disadvantageous for making tea chiefly, it appears, by requiring the heat to be longer maintained in preparing the infusion. Tea is habitually made of excellent quality and with economy, in some families, by means of spring water of a high degree of permanent hardness; but then the infusion is continued for half an hour, and the temperature maintained near the boiling point during that period. The tea for the Greenwich pensioners is infused in a large copper, surrounded by a steam case, with water from a well in the superficial gravel, of 24 degrees of hardness, of which 18·6 degrees are permanent. But in the private residences adjoining it is found necessary to use carbonate of soda for softening, with the same water, in the absence of the efficient means of infusing described. Where any great loss of strength of the tea infusion has been observed, in passing from a soft to a harder water, it may be probably referred to the circumstance that the mode of infusing has not been properly adapted to the hard water. The use of hard water must on this account be attended with a frequent waste of tea. The rapid process of infusion generally employed in London indicates the use of a comparatively soft water. The water to which M. Soyer gave a preference for tea-making, even over distilled water, in experiments reported to the General Board of Health, was the London deep-well water. This is usually softer than Thames water after boiling, and contains, in addition, a sensible quantity of carbonate of soda, to which its superiority is probably due in part. The water of the Trafalgar Square deep well has an original hardness of 5·4 degrees, which is reduced to 1·1 degree by boiling. No great objection can be taken to the use of the London water for other culinary purposes. The presence of much sulphate of lime in water makes it unsuitable for cooking vegetables, owing to the tendency of that salt to form an insoluble compound with their legumine; but this effect is insensible with Thames water."

168. Mr. Bateman refers to the evidence of M. Soyer before the Board of Health, substantiating, as he considers, an economy in cooking. 55–63.

Mr. Hawksley coincides in opinion with the Chemical Commission, and refers to the fact that the London water, and all chalk waters, are very soft after they are boiled; adding that for manufacturing and many other purposes water is boiled, and also for many domestic purposes. 2511.

Mr. Rawlinson considers there would be great economy in household purposes by the use of soft water. 1345–6.

1457–61. Mr. Way also thinks soft water would be economical for cooking purposes. But he adds:—

"Hard water makes better tea than soft, although this is contrary to the general impression. The truth is that soft water makes a darker coloured tea, and dissolves a quantity of bitter extract, which makes the tea strong; but to a refined taste hard water gives much the best flavour, as it leaves the disagreeable matter undissolved."

6267–8. Dr. Frankland, while preferring generally soft water, states that boiling the London water causes it to lose more than half its hardness. As to making tea, he says: —

6359–61. "It is generally held that soft waters make better tea than hard waters, but I do not think that, as an abstract proposition, that is the case. I think that both waters are capable of making equally good tea, but the difference depends upon the length of time that the brewing is conducted. A hard water requires to be longer in contact with the tea at an elevated temperature than a soft water does, and there may be some influence of that kind in dyeing, so that by prolonging the operation you get an equally good result, and it may be perhaps in some cases a better result from hard water than you can get from soft water.

"What is the case with regard to brewing?—With regard to brewing, the case I think is this, that where you want to brew a pale ale it is absolutely necessary to have hard water, and not merely hard water, but water that is permanently hard, that is, water which contains sulphate of lime; but in brewing any other kind of ale, where the colour is not of importance, probably soft water is best to be used as extracting a greater amount of matter from the malt.

"In brewing tea with the London water, which I suppose would probably be softened down to six or seven degrees of hardness, or seven or eight degrees at all events, if the boiling has been continued for half an hour, the length of time during which the tea ought to be brewed to get the most delicate beverage is not more than five minutes, and therefore with a very soft water like that supplied to Manchester it ought not to be more than two minutes. In fact I remember that the best tea was obtained there by pouring the water on to the leaves and almost immediately off again. If you allow a soft water to remain upon the leaves for 10 or 15 or 20 minutes you get a bitter principle out of them, which is unpleasant to me, although I believe it is pleasant to some tea drinkers. Some tea drinkers think that kind of tea the best, and that is more easily got out by soft water than by hard, and therefore from that point of view it might be said that the tea would be more likely to be spoilt by hard water than by soft."

App. D. He further adds that a constant supply of hot water has become almost a necessity in every household, but refers to the difficulties thrown in the way of its attainment by the use of hard water, owing to the formation of thick calcareous crusts in the heating apparatus.

7124. Dr. Miller says:—

"I think that one of the principal objections to hard water is the manner in which deposits take place from it when it is used in boilers. There is always, in our chalk districts, a considerable deposit of hard adherent fur in the inside of boilers, kettles, kitchen ranges, and so on, which in time chokes the range and obstructs the passage of heat, and may occasion accidents. That seems to me to be one of the serious practical inconveniences from hard water which I do not think has been prominently touched upon.

"No inhabitant of London can be unacquainted with that inconvenience?—No doubt they are, and I suppose they feel the inconvenience to some extent."

169. We cannot gather from this evidence any important objection to Thames water, by reason of its hardness, for culinary purposes, except the incrustation in kitchen boilers. With water containing a large proportion of carbonate of lime this would be a serious objection, but practically with the Thames water the inconvenience is not great. A deposit is certainly slowly formed in the boilers or kettles, but it is in most cases of a loose incoherent character, and is removable without difficulty, while in the pipes beyond the reach of the fire very little deposit takes place, and they may remain for years without the necessity for cleaning.

c. For Washing and for Manufacturing Purposes.

170. This is the point on which the greatest stress of the objections to hard water has always been laid; the Board of Health considering that great economy, principally in the saving of soap, would accrue by the substitution of soft water for hard.

171. The Chemical Commission of 1851 say:—

"The injury sustained in washing, from the hardness of the present water supply, is greatly more important; but the estimation of its amount is difficult, and involves the consideration of a variety of circumstances.

"The softer the water the better is it adapted for washing with soap; the earthy salts present causing a definite and calculable loss of soap, which may be taken as amounting, with every gallon of water used in washing, to 10 grains of soap for each degree of hardness of the water. Thus, with one gallon of Thames water, at 14 degrees of hardness before boiling, the loss of soap would be 140 grains and at five degrees of hardness after boiling the loss of soap would be 50 grains; or with 100 gallons of water, the loss in the first case would be 32 ozs., and in the second about 11½ ozs. But such data are not alone sufficient for calculating the saving of soap effected by the use of a soft over a hard water; for soap is used in washing not merely in quantity sufficient to soften the water, but in excess to act as a detergent. The problem is to determine how great the portion of soap lost in softening is, compared with the portion profitably used for washing in the softened water. Such data, however, are not easily obtained. In the bleaching of white goods, as scientifically pursued, soap is not made use of, the process being a series of operations in which the cloth is exposed to lime-water, carbonate of soda, chloride of lime, and acid. The only practice in cotton manu-

factories, where quantities are exactly noted, analogous to common washing, is the soaping of dyed goods; we have found 7 lbs. of curd soap then used with 250 gallons of water, which is nearly 45 ozs. of soap for 100 gallons of water. Now if this water were of 14 degrees of hardness, 32 ozs. more of soap would be required for softening; and of the whole 77 ozs. consumed, 45 ozs. would be available, and 32 lost, which is a sacrifice of nearly 42 per cent. of the soap. With boiled Thames water of five degrees of hardness, 11½ ozs. would be required for softening with the 45 for washing, making 56½ ozs. together, of which 11½ ozs., or about 20 per cent. of the whole soap, is wasted. In the washing of woollens, we find water employed with so much as one-eightieth part of its weight of soap, that is, 200 ozs. of soap with 100 gallons of water. Here the loss of soap by using water of the two different degrees of hardness referred to, being constantly 32 and 11½ ozs., would form a much smaller proportion of the whole soap consumed than before, namely, about 14 per cent. in the one case, and 5 per cent. in the other.

"The maximum loss of soap by the use of Thames water employed cold, would therefore be estimated from such data at 42 per cent. of the soap employed with linens, and 14 per cent. with woollens; or when the same water is softened by boiling, at 20 per cent. with linens, and 5 per cent. with woollens.

"With woollens the loss is too small to entitle it to further consideration, particularly when it is also known that the proportion of woollen articles washed is very small with the poorer classes who frequent the public wash-houses; not more it is believed than two or three per cent. of their whole washing.

"Nor is it to be supposed that in the washing of linen a loss of 42 per cent. of soap is necessarily sustained in all cases. Carbonate of soda is generally employed by laundresses in London to soften water for washing. Indeed, this salt is used in the public wash-houses in a considerably larger proportion than is necessary to precipitate the hardening salts of lime, on its own account, as a powerful detergent, particularly in the first boiling of the linen, and is not omitted although the water is soft, as with the Trafalgar Square water used in the St. Martin's public wash-houses. This use of soda does not appear to be attended by any injury to the linen, with the excellent means of wringing, by which the discoloured water is got rid of, and the abundant supply of cold water for rinsing, which are provided in these establishments.

"The proportion of dyed articles washed by the poor is small, and the colours are generally of a permanent kind which resist soda. In all their washing of woollens and coloured cottons, as well as white cottons, soda is in consequence equally used.

"The following opinion of Mr. W. Hawes is recorded in the evidence upon this subject collected by the General Board of Health, that 'Since the manufacture of crystals of soda at a very low price, and its 'almost universal use in washing, the waste of soap from washing in hard water has been very trifling. 'The quantity of soda used to soften water, as it is called, is a source of expense, but of a trifling amount.' This appears to be strictly true, at least of the washing of the poorer classes as conducted in the public washhouses.

"In regard to the extraordinary injury and wear of linen from London washing often observed, and which has been ascribed to the hardness of the water, it may be remarked, that no such injury to the linen occurs in many private laundries, where handwashing only is practised, and the use of chloride of lime and acids entirely avoided. It is most marked in the larger establishments, where much of the washing of the metropolis is conducted.

"It is in the more careful washing for the middle and upper classes that the advantages of soft water become fully sensible. In the digestion of linen in hot water with soap and carbonate of soda, preliminary to the proper washing, the hardness of the water can only occasion a trifling loss of soda; but afterwards in the wash-tub, where soda is avoided, the earthy salts must occasion a loss of their full equivalent of soap. It is found proper also to avoid boiling any portion of the Thames water that is used in the wash-tub, or even heating the water above a certain point, for the carbonate of lime precipitates on the linen, carrying down the colouring matter of the water with it, and producing stains which there is the greatest difficulty in afterwards removing from the linen. The colour from the water is thus indeed fixed upon the cloth, by the precipitated lime, with the tenacity of a mordant. The evil of the hardness of the water is therefore aggravated by the flood-tinge or clay-colour which the London waters often exhibit for several months in the year.

"The number of gallons of water generally used with a certain weight of soap appears also to be considerably greater in London washing than in the practice of the Lancashire bleachers, so that the waste of soap from hardness cannot fall below, but may exceed, the previous estimate.

"In the washing of the person the saving of soap by the use of soft water is most obvious. For baths soft water is most agreeable and beneficial, and might contribute greatly to their more general use. Its superior efficiency to hard water in washing floors and walls is calculated also to promote a greater cleanliness in the dwellings of all classes, both within doors and externally. While in the occasional domestic washing of linen, the smaller preparation necessary for washing in soft compared with hard water, the saving of soap which would then be sensible to its full extent, and the more easy and agreeable nature of the operation, would make a supply of soft water in a high degree desirable. The use of soda in washing would be gladly avoided by most housekeepers, owing to its injurious action on the colours of certain prints, and the permanent yellow tinge and weakness of fibre which it may occasion even in white linens when exposed to heat before the soda is entirely washed out, as in ironing. A strong desire exists to avoid its use, and where soda is avoided there is no doubt that a saving of about one-third of the soap would be made by washing linen in water entirely soft; supposing the comparison to be made with water of the ordinary hardness of the London supply, but of which one third part was previously softened by boiling. The saving in labour would be even more considerable, if the comparison be still made between washing in soft water, and washing in hard water without the aid of soda."

172. Mr. Bateman thinks there is great advantage and economy in using soft water, because it produces a lather with a less amount of soap; and he refers to the saving effected in Glasgow and Dublin after the introduction of soft water supplies. He estimates the saving in the former of these cities to have amounted to 36,000*l.* per annum. He quotes evidence by Mr. Hawes and by Dr. Clark on the same subject, and also mentions the experience in his own family. 55–63. 66–80.

Mr. Hawksley states that the quality of water most suitable to a large population depends very much on their habits and their necessities with regard to trade and manufacturing purposes. In the north of England, where the great manufactures of the country are concentrated, it is very important the water should be soft, its quality 2504–15.

in other respects being a minor question. He explains the preference for soft water in the manufacturing districts. He points out, however, that the saving of soap is often much exaggerated, the error of calculation in this respect being often enormous. In dyeing, hard water is sometimes advantageous as regards certain colours.

1345–6. Mr. Rawlinson explains that great economy would result in manufactures by the use of soft water, and also refers to its superiority for personal ablutions.

1499, 1520. Mr. Way considers that for most manufacturing purposes soft water has a great advantage. In dyeing they much prefer soft water; the quantity of soap used in this trade is immensely large. For the dyeing proper, however, particularly with bright colours, harder water is considered preferable. At Lyons hard water is preferred. Still the washing process is so much the more important that on the whole soft water is preferable. For brewing soft water is not good, except for the darker kind of beer. It will not brew bitter ale or light coloured beer; all the Burton ales are brewed with hard water. For London porter, however, soft water might be desirable. In washing, the saving of soap and of linen from soft water are undeniable. In scouring cloth this is of much importance. He believes the manufacturers of Yorkshire went to the valleys of the Aire and the Calder more for soft water than for the supply of coal; though now the streams are so foul they cannot use them.

2185–97. Mr. Duncan agrees that soft water is preferable for general manufacturing purposes.

Dr. Letheby gives evidence on this point as follows:—

3938–40. "Are you acquainted with the evidence which was given before the Board of Health, with regard to the economy in the use of soft water, some years ago?—Yes.

"What opinion have you formed with regard to that?—My opinion is, that it is very much exaggerated, and that exactly coincides with the opinion which the chemical commissioners, Messrs. Hofmann, Graham, and Miller, formed of it. I think that those statements which were made by the old Board of Health upon that subject were founded upon wrong premises. They were founded upon the supposition that water was always taken of the degree of hardness that it has in its unboiled condition.

"You would separate the permanent from the temporary degrees of hardness?—Yes, the permanent hardness being that upon which I founded my calculations, while the non-permanent is that upon which the Board of Health founded their calculations; and this makes a good deal of difference in the result."

2646–719. Dr. Playfair states, at considerable length, his opinion that soft water is generally preferable for detergent and manufacturing purposes. He says:—

"Hardness is of the greatest importance as regards the economical use of that water, and its comfortable use for the population. The effect of a hard water upon its ordinary detergent use is seen in the waste of soap and the difficulty of washing which washerwomen experience, and they are far more important members of the industrial community than is generally supposed.

2647. I gather from your statement also that the mass of the population would be likely to be more cleanly, and therefore more healthy, if the water were soft, and less soap were used, than if the water were hard, causing a great difficulty in producing lather?—Yes.

2648. And it is therefore more conducive to health?—Yes, a more thorough cleansing takes place.

2649. So that if it were a question of obtaining either hard or soft water for a population at the same price, you would give the preference largely to soft water, taking all the purposes into consideration?—At a very great difference of price I would give the preference to soft water, because the economy in manufactures is so enormously great with soft water.

2650. Could you give us any illustrations of the economical use of soft water in manufactures?—I could give an instance to show the great difference caused by even a small per-centage of additional impurity in a water. In the River Clyde there is a dam or weir across the river to dam up the fresh water for the supply of the manufactories; below this dam several sewers come in and deteriorate the water very slightly as regards analysis, but very greatly as regards its effect upon manufactures. A piece of calico above this dam, although the difference in value of the water is only about half a grain per gallon of impurities, requires four ounces of madder less to bring it up to the same dye; below the dam of course it requires four ounces more, and the difference of that to an ordinary work where they dye 1,000 pieces a day is 1,562*l.* in the year.

2651. Do you mean that that represents the difference between the use of the water above this dam and below?—Yes, the calico printers dyeing with the water above the dam would save 1,562*l.* a year, supposing they dyed 1,000 pieces a day, which is what good works would do, and they would have to spend that money if they used the water below the dam.

2652. Therefore, that is not a distinction between softness and hardness, but a question of purity or impurity?—In this case the deterioration of the water is owing to its containing iron; the water contains half a grain of oxide of iron below the weir more than it does above.

2705. You have referred to the effect of soft water in the use of dyes; could not that question be looked as in two points of view, one with regard to the economy in the use of the dyes, and the other with regard to the effect of the dyes themselves?—Yes; it has three influences upon dyeing: first, upon the original bleaching of the cotton; secondly, in the waste of the material used in dyeing; and thirdly, in the cleansing or clearing operations after the dyeing is completed; and in all those cases a pure water is preferable to a water containing any hardening matter.

2706. Does not water of a moderate degree of hardness bring out many colours better than soft water?—I have never found it so; I have carefully experimented, and I have found that distilled water brings out the best colours, and in all the experiments that I have made I have found that hard waters do not bring them out so well; but you will get plenty of manufacturers and dyers to tell you differently, and for this reason, that a dyer gets thoroughly accustomed to the water with which he operates, and he uses his materials and his mode of operation to suit that water; and if any other water is brought to him suddenly, seeing he is guided almost entirely by experience, he will get a worse result with a better water, because he is not accustomed to use it; and it requires the experiments of a chemist to elicit those sources of error. Every brewer who has been accustomed to brew with hard water will inform you that hard water is much better and

more suitable for brewing, whereas a brewer who has been accustomed to brew with soft water will tell you that soft water is better than hard; manufacturing use is entirely a matter of experience, in which people suit themselves to the case before them.

2707. Are you acquainted with the experiments of Dupasquier with regard to the effects upon dyes in using distilled water, river water, and spring water?—No, I am not. I may mention that I was once the chemist to large calico printing and dyeworks, and that therefore my attention has been practically directed a good deal to that question. In early life I was chemical manager to Messrs. Thompsons' calico printworks in Lancashire.

Dr. Parkes and Mr. Simon agree with the opinion of Dr. Playfair. Mr. Firth and Mr. Jubb, cloth manufacturers in Yorkshire, state that they find an economy, the one of 25 per cent. and the other of 15 per cent., in soap for scouring by the use of soft water, and they prefer it for dyeing purposes, though for some colours they find hard water do as well; but it appears that their hard water contained iron, in the one case in considerable quantity, and that the total amount of solid residue was 50 grains in the gallon. 3138. 2782. 5212. 5320.

Dr. Frankland considers there is great advantage in the use of soft water in manufactures and for cleansing purposes. He explains the disadvantages of hard water for personal ablutions. As to the saving in soap, he says: 6261. 6277. 6357–8.

"You have, I presume, seen various estimates of what might be the saving if soft water were used instead of hard water?—Yes. 6368–9.

"Do you think that those estimates are generally correct, or do you consider them as rather in excess?—I think that there ought to be considerable latitude allowed in them. I do not think that the estimate would be correct as regards the amount of soap used in personal ablution, for the reason which I have just now mentioned. It is somewhat different in the case of washing linen. Supposing that the water were not softened with soda, then I believe that the estimate would be correct, because you must get the whole of the lime salts precipitated in the water before this washing of the linen can be effectually carried out."

He further expresses his opinion that the advantages of temporary over permanent hardness have been considerably overrated; as water used hot for domestic purposes is either not boiled, or boiled for too short a time to produce the full softening effect. App. D.

Dr. Odling thinks that except for drinking purposes soft water is on the whole preferable to a hard or even to a moderately hard water like the Thames. For manufacturing purposes soft water has great advantages over hard, except in very special cases. 6437–8.

Dr. Miller says there is no doubt that soft water, for all purposes except dietetic, is preferable to hard. There would be a certain saving in soap, but he thinks the amount of saving has been somewhat exaggerated in some estimates which have been made regarding it. As regards personal ablution, undoubtedly soft water is far more agreeable than hard. 7046–53.

Dr. Angus Smith concurs in the advantage of soft water for manufacturing purposes, but he considers the saving in soap has been somewhat exaggerated. 7218–22.

Mr. Heron says that in Manchester the supply of soft water for manufacturing purposes is an enormous benefit. There are many cases where calico printers and others pay a very large sum per annum to the corporation for the water in preference to water which might be obtained at a less cost probably, but which is not of the same quality. The income derived from the water sold for trading purposes is very large, and it is by that income alone that the corporation are enabled to supply the water at the low price they do for domestic purposes within the city. 7343.

173. There is no doubt that this evidence is conclusive and cogent as to the great advantage of soft water over hard for washing and, with some few important exceptions, for general manufacturing purposes; and if we were treating of the supply of a town like those in the manufacturing districts of England, where large quantities of water were required for these purposes, the objection to the present supply would assume a more serious aspect. But the amount of manufacturing industry in the metropolis, of a kind to demand large supplies of soft water, is exceedingly small in proportion to the population, and it must be recollected that the softening influence of boiling largely diminishes the evil. To these exceptional cases, also, the softening process of Dr. Clark would be easily applicable.

There is no doubt also that in personal ablutions and washing generally the use of soft water is more pleasant and economical, but we think the latter advantage has been much over-estimated. The soap is usually applied out of the water, and therefore it is with the small quantity of water adherent to the object washed that we have to deal, and not with the total quantity used for rinsing to remove the soap. It is certain, however, that when a soft water or rain water can be obtained for these purposes it will always be preferred.

All the witnesses have deposed to the general great economy of soft water for most manufacturing purposes, but we find it difficult to reconcile the opinions of some of the witnesses respecting the advantages in dyeing (except on the score of economy) with the fact that the largest and most important manufactories in France for silks, woollens, and

cottons have risen in Lyons, Rheims, Amiens, and Rouen—all using hard waters, and the three latter towns situated in chalk districts. Dupasquier, a well-known chemist, when called upon some years since to report on the waters of Lyons, showed as the result of his researches that waters of a certain degree of hardness were preferable generally for dyeing purposes, so far as regarded brilliancy of colour generally.

On the whole we cannot see that the advantages of soft water in this respect are of sufficient importance to justify going to a great distance to obtain it, in place of the ample supply nearer at hand.

Other Elements of Comparison between Hard and Soft Waters. Action on Lead and Iron, &c.

174. When speaking of the quality of water proposed to be supplied by Mr. Bateman's plan, we have alluded to the danger which may arise in some cases from the action of soft water on lead; and there is, further, the inconvenience of its acting on the iron pipes, leading to the deposition of concretions, interfering with the flow, and eventually destroying the pipes. Several witnesses have deposed to this action, especially Mr. Duncan, who states that at Chorley "they had to take up and relay a number of pipes "in the town, because they had become choked up in consequence of corrosion." In the same way the pipes at Grenoble became so damaged and choked after ten years' use that they had to be removed. A similar thing, but in lesser degree, happened at Cherbourg. Like, however, the action on lead, this action on iron is uncertain and irregular, and may most probably be guarded against by artificially coating the pipes.

From both these evils the water supplied from the present sources is perfectly free. The Chemical Commission of 1851 say: "The water at present supplied may be circulated "through leaden pipes, or preserved in leaden cisterns, with an unusual degree of safety. "The corrosion of water cisterns in London is generally occasioned by the mud which "subsides to the bottom. This corrosion is not attended by any sensible solution of "lead in the water. The London water may indeed be said to exert the least degree "of solvent action upon lead.

"The circulating system of iron pipes appears also to receive a certain amount of "protection from the alkaline character of the present supply. The erosions and bulky "deposits in cast-iron pipes, which have given great trouble in the distribution of certain "waters, are quite unknown in London."

Further, in considering the relative advantages of a water in a dietetic point of view, it must not be overlooked that hard water is less absorbent of gases and of organic impurities, and is therefore less liable to change than soft water. This, it is true, is in most cases a matter of very little importance, but in large towns, and with a poor population, it is to be weighed in the balance.

The Commission of 1851 say: "Putrefactive decomposition appears also to occur less "rapidly in hard than in soft water, and hard water seems to be the more easily preserved "in reservoirs or tanks without deterioration for a short time."

Artificial Softening.

175. It has been frequently suggested that the hardness of the London waters might be removed by the softening process invented by the late Dr. Clark, who has given a full account of it in his letter, Appendix G.

The Chemical Commission of 1851 had so good an opinion of this process, that on the ground of its peculiar applicability to chalk waters, they recommended that these waters, so softened, should be resorted to for the supply of the metropolis. As to its application to Thames water, they, after witnessing certain trials made at the Chelsea Waterworks, came to the conclusion that it was not attended with any peculiar difficulty on the large scale, and that the softening of Thames water in its ordinary condition to a point under four degrees of hardness was perfectly practicable. They estimated that the cost would be about 20*s*. per million gallons. They added, however, the following remarks:—

"The liming process, even when combined with filtration, proved to be unequal to remove the yellow flood tinge of Thames water, nor did it appear to abate an objectionable taste of vegetable matter which the water also then possessed. Had the result been different, the grounds for the adoption of the softening process would have been most cogent. But it seems that it is not to river waters that this elegant and useful purifying process is most advantageously applicable."

4026. Mr. Muir states that the New River Company have been prevented from adopting this process by the difficulty of accomplishing it on a very large scale, and also by the risk of deposit in the pipes. He adds:—

"I think, taking into account the fact that the temporary hardness of the New River water is so much greater than its permanent hardness, that the gain would not be very great; and from the difficulty of applying the

process on a large scale, and the large quantity of water used for sewer flushing and street watering and other purposes (where the softening process is really useless), we have not much encouragement to go into the thing."

Mr. Homersham tells us that he has applied the process with perfect success to chalk waters supplied at various places; the current expenses being about 27*s.* per million gallons. He adds, however, that a river water is not adapted for being softened by it. He says, alluding to the trials at the Chelsea works:— 6762 et seq.

"The effect was this, that if the water operated upon is filtered water, so that it is clear before you apply the lime, the deposit settles quickly and you have no difficulty; but if the water contains any clay or is discoloured by a flood, as river water frequently is, the organic matter in the water, or whatever it may be which discolours the water, mixes with the crystals of the carbonate of lime and alters the specific gravity, and they do not fall down, but keep floating about in the water. The result is, that you must filter that water after it is softened." 6812.

176. Apart from the expense of this process (which would be very large for the whole supply of London), it does not appear to be applicable to the Thames waters on a large scale. It appears more suitable for small districts supplied from chalk wells, or for private use in manufactories where soft water is specially required.

On the Organic Impurities and Contamination of the Thames Water.

177. We now approach the more difficult part of the subject. If the waters of the Thames had no impurities beyond the solid mineral contents, the question as to their wholesomeness and general suitability for the supply of the metropolis would be easily disposed of.

But attention has been called strongly to the *organic impurities* contained in Thames water, which, though more indistinct in their form, and less appreciable in their quantity, are said to be more deleterious in their nature, and to render the water, if not dangerous and unwholesome, at least liable to suspicion.

178. It is easy to understand how streams and rivers may become contaminated with organic matters. The pure rain or spring water, flowing over the surface of the land, will dissolve vegetable matter with which it comes in contact, and if the land be highly cultivated there will also be taken up animal refuse from the manures, or from the droppings of live stock kept upon the farms. But the contamination may go further than this. In spots where the population is collected into villages, the excretions from the inhabitants will often find their way, to a greater or less extent, into the streams forming the natural drains of the land; and in the cases of large towns this effect is artificially aided by the establishment of waterclosets and systematic sewerage.

179. The waters of the Thames are of course liable to organic contamination from all these sources, though perhaps not in so great a degree as is generally supposed. In the first place, as regards the matters, vegetable and animal, washed from the land, it must be remarked that although the greater part of the basin of the Thames is cultivated, and some of it very highly, yet nearly half the area consists of porous permeable strata, such as chalk, oolite, and sand; and that the waters falling on these, except on occasions of large and sudden floods, will be rapidly absorbed, filtering through the earth and going to form the springs. It is from the retentive soils that the washings will be most plentiful and most charged with organic matters.

As regards the excretions from the inhabitants, the basin of the Thames above Hampton is comparatively thinly populated, from the absence of minerals and the non-attraction of any large manufacturing interests. Taking the area of the watershed above the point of intake of the companies, we find by the Report of the Rivers Pollution Commission that the number of inhabitants is about 888,000, and the area is 3,676 square miles, which gives about 230 persons per square mile, or rather less than three to an acre. Then a very large portion of the inhabitants live in villages or small towns dispersed about the agricultural districts, where no regular sewerage is either applied or required, the produce being considered valuable and used for direct application to the land. The population in towns of above 2,000 inhabitants amounts to only about 212,000, and it is only in the larger of these towns, such as Oxford, Reading, Windsor, and probably some few smaller places, that human excrements can be considered as being turned systematically into the stream; and even in some of these cases, from the incompleteness of the drainage arrangements, the effect is at present only partial. Thus it may be shown that only a portion of the inhabitants of the basin can effectively contribute to the sewerage contamination of the river. 2591–5.

180. But though for these reasons we believe that the organic contamination of the Thames is much less than is commonly imagined, still it would be sufficient to do great mischief, were it not for a most beneficial provision of nature for effecting spontaneously the purification of the streams. Some of the noxious matter is removed by fish and other animal life, and a further quantity is absorbed by the growth of aquatic vegetation; but in addition to these abstractions, important changes are effected by chemical action. The organic compounds dissolved in the water appear to be of very instable constitution and to be very easily decomposed, the great agent in this decomposition being oxygen, and the process being considerably hastened by the motion of the water. Now as such waters always contain naturally much air dissolved in them, the decomposing agent is ready at hand to exert its influence the moment the matter is received into the water; in addition to which the motion causes a further action by the exposure to the atmosphere; and when (as in the Thames) the water falls frequently over weirs, passes through locks, &c., causing further agitation and aëration, the process must go on more speedily and more effectually.

The effect of the action of oxygen on these organic matters, when complete, is to break them up, to destroy all their peculiar organic constitution, and to rearrange their elements into permanent inorganic forms, innocuous and free from any deleterious quality. This purifying process is not a mere theoretical speculation; we have abundant practical evidence, which we shall hereafter refer to, of its real action in the Thames and other rivers.

181. The question now naturally arises, can we not, by careful analysis of the Thames water, discover what quantity of organic matters it contains; what is the nature and character of such matters; and how far they are deleterious or otherwise? We have endeavoured to arrive at a solution of this question, but unfortunately without much success. The inquiry seems beset with difficulty. The organic matter is present only in very small quantities, and in shapes and conditions which are very difficult to identify and to reduce to actual measure. The treatment of them is still a problem in chemical science, only now beginning to be effectually studied, and the most eminent chemists are yet by no means agreed either as to the processes most proper to be followed in the analyses, or as to the value and bearing of the results obtained.

It does not follow that all organic matter in water is prejudicial; great mistakes have arisen on this point, as it is often given out that the very suspicion of organic contents of any kind in a drinking water should disqualify it for use. But almost all our drinks other than water owe their distinctive qualities to the varieties of their organic contents, and hence it is clear that the presence of organic matter *per se* is not necessarily prejudicial. It is however necessary, in potable waters which contain organic matter, carefully to distinguish between such combinations as are innocent and such as are noxious; and here lies one of the greatest difficulties.

We now proceed to state the evidence before us on the quality, as regards organic contents, of the water supplied to London.

Earlier Analyses.

182. The Scientific Commission of 1828 called attention to the organic impurities of the Thames water, as taken in the immediate neighbourhood of the metropolis; and added the following general remarks on its salubrity:—

"The statements which have been made respecting the insalubrity of the Thames water as supplied by the companies have also been considered by us, and although, from the few cases which have been brought before us of disorders imputed to this cause, we do not feel ourselves warranted to draw any general conclusions, we think the subject is by no means undeserving of further attention. There must always be considerable difficulty in obtaining decisive evidence of an influence, which although actually operating to a certain extent as a cause of constitutional derangement, may yet not be sufficiently powerful to produce immediate and obvious injury. It cannot be denied that the continued use of a noxious ingredient in diet may create a tendency to disorders which do not actually break out until fostered by the concurrence of other causes, for we unquestionably find an influence of the same kind exerted by other agents which occasion merely a certain predisposition to disease, and of which the immediate operation must therefore be extremely insidious and difficult to trace. It is obvious that water receiving so large a proportion of foreign matters as we know find their way into the Thames, and so far impure as to destroy fish, cannot, even when clarified by filtration, be pronounced entirely free from the suspicion of general insalubrity."

App. A F. The Chemical Commission of 1851, who tested the water with all the chemical skill then attainable, report in the Thames water (then still taken within the tideway) a quantity of organic matter varying from 1½ to 3 grains per gallon, on which they remark as follows:—

"The soluble organic matter from two of the Thames waters was submitted to ultimate analysis, and found to give 0·105 grain of nitrogen in the Grand Junction water, and 0·031 grain of nitrogen in the Southwark

and Vauxhall water. The existence of nitrogen is generally supposed to imply the animal origin of organic matter, and on such evidence a minute and probably unimportant portion of animal organic matter would be admitted to be present.

"None of the waters had any marked taste or odour, nor betrayed any indication of putrescence, either when first taken up or after being kept in bottles for several weeks at a temperature between 50° and 60°; nor even after remaining in close vessels for two weeks at 80°.

"In these waters when submitted to microscopic examination no animalcules were observed in any case. But the period of the year was not that at which any considerable development of animal life is to be looked for."

They allude to the colour and contamination to which the river is liable in the late autumn and early winter, from the extensive decomposition of vegetable matter, which they state to be a serious evil; but they appear to draw, in a sanitary point of view, a broad distinction between this and organic matters of animal origin, on which they remark as follows:—

"As the main drain of a large and populous district, the Thames becomes at all seasons polluted by the sewerage of several considerable towns, and by the surface drainage of manured and ploughed land. At the same time, we doubt whether the existence of organic contamination from town drainage is at present perceptible in the Thames above the reach of the tidal flow, or amounts there to a sensible evil. The indefinite dilution of such matters in the vast volume of the well aërated stream is likely to lead to their destruction by oxidation, and to cause their disappearance. The river may reasonably be supposed to possess, in its self-purifying power, the means of recovery from an amount of contaminating injury equal to what it is at present exposed to in its higher section."

They add further observations tending to justify a recommendation that the supply should be drawn from a point above the tideway.

Messrs. Hofmann and Blyth's analysis in 1856, made after this recommendation had been carried out, in pursuance of the Act of 1852, showed in a striking manner the advantage of the change. The chemists found that the hardness and mineral contents had undergone little variation; but in regard to the organic matter they reported as follows:— App. B G.

"*A very considerable diminution, however, is observed in the amount of organic matter.*

"In fact, in 1856 the water supplied to the metropolis contained not more than one-half of the organic matter which was present in the year 1851.

"This result is certainly not accidental. The diminution is not merely an average result, but uniformly observed throughout. The waters examined in 1851 were taken in January; those investigated in 1856, partly in January and partly in April. The diminution of the organic matter cannot therefore be due to the influence of the season. Nor can it be due to any difference in the mode of determining the organic matter in 1851 and 1856. These determinations were made by exactly the same method; for it so happens that the analytical part of the inquiry in 1851 which refers to the organic matter was likewise made in the laboratory of the Royal College of Chemistry. The diminution is obviously partly due to the alteration of the localities from which many of the companies derive their supply. The Grand Junction, the West Middlesex, the Southwark and Vauxhall companies, formerly supplied respectively at Kew, Barnes, and Battersea, derive their present water from Hampton; the Lambeth Water Company used to take their water at Lambeth, but have now erected extensive works at Thames Ditton. The diminution of the organic matter in the London water supply is, however, by no means confined to the companies that have changed the locality of their source, and it must therefore be attributed in a great degree to the considerable improvement which has taken place in the collection, filtration, and general management of the supply of water to the metropolis."

The analyses of Letheby, Odling, and Abel, in 1867, state that the quantity of organic matter in the filtered water could not have exceeded one grain per gallon, and shew the ammonia to be almost infinitesimally small. The average total quantity of organic matter in the water supplied in 1867 appears only about two-thirds of that in 1856, and only about one-fourth of that in 1851, showing the beneficial change effected from further improvements in the supply. App. A H.

In the Returns of the Registrar General, there are now given monthly reports by Dr. Frankland on the condition of the waters supplied by the different London companies. The analyses which accompany these reports show a general agreement with those just referred to. As, however, they are elaborated on a principle not ordinarily employed, it is not easy to compare them with those of other chemists. They give very careful and definite determinations of organic matter, but on the value of the mode employed, and on some of the inferences, there is a difference of opinion amongst men of science; and we shall presently have to make some remarks on this subject.

183. We have had before us many witnesses conversant with the subject, including some of our ablest chemists, and have endeavoured to ascertain fully their opinions on this question, which we will now give, as far as practicable, in their own words.

Evidence on the Organic Impurities of Thames Water.

Chemists and Medical Men.

184. Dr. Lyon Playfair, Professor of Chemistry in the University of Edinburgh:—

2681. Will you allow me to ask you whether in soft water the same proportion of organic matter would not be more injurious than in water of an ordinary degree of hardness, and what would be the effect of the presence

of organic matter in such water?—The effect of organic matter in the water depends very much upon the character of that organic matter. If it be a mere vegetable matter, such as comes from a peaty district, even if the water originally is of a pale sherry colour, on being exposed to the air in reservoirs or in canals leading from one reservoir to another, the vegetable matter gets acted upon by the air and becomes insoluble, and is chiefly deposited, and what remains has no influence on health. But where the organic matter comes from drainage it is a most formidable ingredient in water, and is the one of all others that ought to be looked upon with apprehension when it is from the refuse of animal matter, the drainage of large towns, the drainage of any animals, and especially of human beings.

2682. No doubt a large proportion of organic matter of such a nature would be injurious, but in ordinary cases of a river, such as the Thames above London, the action of the aëration of the water would be in that case to destroy any moderate amount of organic matter, would it not?—It would gradually, but such matter becomes insoluble more slowly than the matter of which I have been speaking; and in any case the presence of it is dangerous, and as one does not know the stage to which the oxidation has gone, the presence of any such animal matter in water is always most objectionable. It is impossible to tell at what stage it is by a mere general examination; by a chemical examination you can do so, but the presence of the most highly oxydised form of organic matter when it passes into the stage of nitrate is, I think, quite sufficient to condemn the water, because you are never sure whether it has fully passed into that stage.

2683. Is it not considered that by the time the Thames water, with which London is now supplied, reaches the delivery pipes all organic matter is converted into the state of nitrates and nitrites?—I think that the evidence from the cholera of last summer was quite conclusive on that point, that it was not.

2684. That was confined to one particular district, was it not?—Yes.

Mr. Simon, Medical Officer to the Privy Council:—

2751. You of course have analysed, and you are well acquainted with the quality of the London water?—Yes.

2752. What is your opinion as to its character?—Judging by chemical analyses, performed on it in what I may call its normal state, I am not aware that there is much fault to be found with it.

2753. You are speaking now of all the water supplied by the various companies?—Yes, speaking quite generally. Speaking of it in its broad ordinary chemical characters, as it would be reported on from a chemical laboratory, I should say it is a fair water supply.

2754. Are you now speaking of the whole supply of the metropolis?—Yes, speaking generally of it. But what I thus say of its average chemical constitution in its normal state does not touch the question of the water's liability to accidental very dangerous pollutions. There are dangerous qualities of water supply, with regard to which, so far as I know (but I do not speak as a skilled chemist), chemists are totally unable to measure, even to demonstrate, the fatal influence that a water may have. A water may be, for instance, capable of spreading cholera, but chemists be unable to identify the particular contamination which produces that effect.

2812. My practical point is, that what one has to do is not to take water out of a reservoir or out of a tap and give it to a chemist and say, "Tell me, is this wholesome water"? What one has to do is to guard the supply with the utmost strictness against every foul admixture. It ought to be made an absolute condition for a public water supply, that it should be incontaminable by drainage.

2837. Have you, apart from the question of sewage, considered the condition of the Thames basin as a gathering area, having regard to the high state of cultivation of the land and the use of manures, artificial and other, and the washing of water into the Thames, what the effect upon the water would be for domestic purposes?—The earth is a most powerful absorbent and disinfectant of the materials used as manure, and I do not think that practically any important danger would attach to the outflow from cultivated lands.

7135. I think when you were examined before you were asked your opinion as to the effect of sewage contamination in rivers, and after how long a period, and at what distance of flow, the river would get rid, if at all, of that sewage contamination; have you formed any opinion upon that point?—I cannot venture to answer that question with any confidence; it is a very difficult question to answer.

7136. But are you of opinion that the water of a river which had been under the influence of such contamination would ever after be a safe water for domestic purposes?—The answer to the question, if it is to be absolutely correct, must vary with the quantity of sewage, the volume of water, and the distance between the point of contamination and the point to which the question applies.

7137. Supposing that sewage is discharged from one of the sewers, say, at Windsor, would it be possible to detect the presence of that sewage seven miles lower down the river, having regard to the volume of water in the river?—I believe it would be absolutely impossible for chemists to discover it, but the practical sanitary question is different. Supposing tape worm eggs to be sent into the river with that sewage, would those tape worm eggs be alive seven miles down? Or, supposing cholera discharges to be sent into the river, or the discharges of typhoid fever, and assuming (which is a frequent pathological opinion) that the respective contagia of typhoid fever and cholera are living germs, would those germs be alive seven miles down? It is not a question whether a chemist would find out the organic matter so much as it is a question whether those particular molecules would still have their property seven miles down. I cannot say that they would not.

7138. Could you detect them at that distance?—Only by their effects.

7139. Might not the same disease be produced from any other cause?—The particular parasite will only come from its particular egg. You would not get hydatids except from eggs any more than you would get chickens without eggs.

7140. Are the Commission to understand you to state that it is impossible for a chemist to discover the existence of sewage at the distance named?—The possibility varies with the conditions I have stated.

7141. If it is not possible for a chemist to discover it, is it not presumptive evidence either that it does not exist, or that if it does exist it is in such minute quantities that it is in no way deleterious to human health?—I am very decidedly of opinion that that principle is not a safe one to adopt as a basis for sanitary regulations in the matter. I think the rule ought to be that no sewage should go into any water that can be used for drinking purposes. I think, even, that allowance should be made for the proper decent taste of people. Water into which sewage has been discharged is, in relation to the matter now under consideration, an experiment on the health of the population, and I do not think that that experiment ought to be tried. Moreover, as a mere matter of taste, people would rather not drink water into which sewage has been discharged, and I think that that in itself deserves consideration.

Dr. Farr, Superintendent of the Statistical Department of the General Register Office, has given us lengthy information as to the outbreak of cholera in 1866 in the East of London, and has put in valuable statistics, &c., thereon. The following extracts will illustrate his general views :— 2845 et seq.

2876. Am I to understand you to say that in those districts where the cholera prevailed very largely the principal cause was the impure water?—I conceive that the cause of cholera existed here, and that the elements of disease from cholera patients were distributed all round London. Cases occurred in every part of London, but in the other districts the mortality was inconsiderable. For instance, in all the districts supplied by the Grand Junction, the West Middlesex, and the Chelsea Water Companies, the mortality was about 3 in 10,000, in those supplied by the Southwark and Lambeth Companies, which were formerly so heavily visited, it was about 6 in 10,000, and in those supplied by the New River Company about 8 in 10,000, but in those supplied by the East London Company from the Old Ford reservoirs it was 79 in 10,000. I do not ascribe the whole of that mortality to the water, but I ascribe a large portion of it to the circumstance that the impurity causing cholera was distributed through the water of that company.

2877. Will you be good enough to tell us what you consider those other circumstances to be?—The density of the population also had an influence. We found that where people were packed very closely together they suffered more than where they were distributed more widely over the ground. We have found also that the condition as determined by the annual value of the houses that the people lived in, their poverty had a considerable influence, but not so striking as I should have imagined it would have had. We found also that the elevation of the ground in which the people were living had a very marked influence. In the first report I showed that the mortality on the low banks of the Thames both on the south and on the north side, was from 100 to 150 per 10,000, but as you ascended on successive terraces the mortality was reduced, and at the higher points it came down to 8, so that the elevation of the soil had a considerable influence. That I have been led to suppose since had a good deal of influence upon the purity of the water also.

2890. Do you think that if this London water could be free from all its impurities it is a good quality water for consumption?—I confess that when I see that this Loch Katrine only contains in 100,000 grains three grains of impurities of any kind, and that it contains no trace whatever of sewage or anything like sewage, I should have greater confidence in water brought in that way from the hills than I should in water taken from the river; at the same time I am not prepared to say that the water from the river, with great precautions as to letting sewage into it, might not be made a very decent sort of water.

2929. As far as your experience goes, are we to take it that this view which is conveyed in the report of Dr. Frankland is one that you concur in, namely, that at the present moment taking his analysis there is nothing that is really bad in the water supplied to London?—Not on that particular day. I should qualify it myself always in that way. I can conceive that the character of the water varies from day to day; it varies with the temperature and with the rainfall, and with a variety of circumstances. All we know is that from the analyses which Dr. Frankland has hitherto made he has come to the conclusion that the water supplied to London has contained something very noxious, but that it did not contain anything noxious at the time that he took it at the mains.

Dr. Parkes, Professor of Military Hygiène in the Army Medical School at Netley :—

I have made a list of diseases all of which are occasionally communicated by means of water, not solely communicated by water, but occasionally. For example, typhoid fevers; of which I have collected about 23 instances of local outbreaks of severe typhoid fever, and some six or eight more, the particulars of which I have not got, are known to me, arising from water impregnated with typhoid sewage, or possibly with simple sewage.

3123. As far as your special observation has gone, in all cases where there has been a discharge of human excreta into water where the parties have been suffering from typhoid fever, that has generated disease in every district where the water has been taken for domestic purposes?—It has not generated typhoid fever in all cases, because in some cases it has generated diarrhœa and dysentery; typhoid fever has prevailed in some cases and not in others, and therefore that is an argument in favour of the view that it requires the typhoid sewage especially to pass into the water for the development of that particular fever, and that simple sewage will not cause it. But the question is surrounded with difficulties; it is so difficult to get reliable scientific evidence that it is still *sub judice*.

Dr. Parkes proposes to divide potable waters into several standard classes. He says :—

I would propose to form a class of "wholesome waters," under which two sub-classes of waters may be included, first, the purest and most wholesome water, which is free from suspended matters and contains very little dissolved organic matters, say under one grain per gallon, and that probably vegetable, and of dissolved mineral matters under seven grains per gallon. That will include all the best waters supplied from the primitive rocks, and from some of the sands which contain under that quantity of mineral matter, and is probably the purest water on the whole which can be obtained in that way.

Then the second sub-class in the first order would be what I would call pure and wholesome water, to which no objection can be taken, I believe, in a sanitary point of view, but which is not so pure as the former. This water is also free from suspended matters, having dissolved organic matter under two grains per gallon, the greater part of that being vegetable. Of dissolved mineral matters it would contain under 12 grains per gallon, consisting principally of carbonate of lime and alkaline carbonates and chlorides. That second sub-class would include the best chalk waters, which are often very free indeed from organic matter. Then the second grand class I would make I would propose to call "useable waters;" waters which cannot, perhaps, be very much objected to, not so good as the former class, but yet which in many cases might be used, and which would not produce, perhaps, any bad effects. Those are all waters with no suspended matters or suspended matters easily separated by the coarse filtration usually resorted to by the water companies. The organic matter would be chiefly vegetable, but it should not exceed three grains per gallon, owing to the diseases which would probably arise if it exceeded that quantity, and if the organic matter is apparently of a mineral origin it ought not to exceed two grains per gallon. Then it should contain mineral salts not exceeding 20 to 30 grains per gallon, and consisting of a class of salts which do no injury to the system, such as alkaline carbonates, alkaline chlorides, chloride of sodium, and chloride of potassium, in less quantity, and possibly a little carbonate of lime also.

3149. The third class would be what I would call "suspicious water," which would be any water with much matter suspended, which would be separated readily by coarse filtration. Such a water as that would in all probability contain either fine particles of mineral matters, which are hurtful, such as clay, or possibly it might contain suspended organic matters very finely divided, and not very readily separable by filtration. It might contain dissolved organic matters vegetable and animal, amounting to about three or four grains per gallon, and mineral matters of large amount, such as alkaline and chlorides, carbonates, and carbonate of lime in large amount, that is to say, perhaps over 9 or 10 grains per gallon, or sulphate of lime or magnesia, and chloride of calcium or magnesium in certain quantities; all those I should consider make a water suspicious; or if it contains any indication of nitrites, nitrates, ammonia, &c., showing that organic matters had passed into the water and had there been oxidized; any indications of that kind I should consider would bring the class under the head of suspicious water. Then the fourth class would be "impure water," which would include any turbid and bad smelling water with suspended matters not easily separated by coarse filtration; also dissolved organic matters above four grains per gallon, especially if of animal origin, large quantities of mineral substances, especially of sulphate of lime and sulphate and chloride of calcium and magnesium, which all give permanent hardness to the water, or large indications of nitrites, nitrates, fatty acids, ammonia, &c., all of which indicate the passage of organic matters, animal in all probability, into the water.

3150. Under which of those heads would you put the London water?—I should put the London water under head No. 3, suspicious.

3151. Would you do that because there are indications of nitrates?—Yes; I should call any water containing large indications of nitrates and nitrites suspicious water. Such indications may, however, come from water not impregnated with sewage, as some soils give off nitrates and nitrites. . . . . I think that the mere presence of nitrates and nitrites in water in small quantities would not be hurtful at all; their importance is as indicating their source, and showing that there must have been contamination, probably by animal inorganic matter, in most cases sewage, and of course rendering the chances of such organic matter passing in in sufficient quantities to affect the health very probable, but when such organic matter has been oxydized, then no doubt it becomes, at any rate in most cases, harmless.

3160. Sewage is the most dangerous parent of those things, is it not?—Yes. But any indication of them should lead at once to an examination, so as to trace the origin of nitrates and nitrites, and the water would be suspicious in the proportion that it contained any large quantity.

3161. It would not be a certain inference that it was from sewage?—Certainly not.

3177. Is there in your judgment an objection to the Thames basin as a gathering area for water by reason of the high state of cultivation in some parts, and from the manuring that it undergoes?—Yes, I think there is a very great objection. No doubt the effect of water passing through a soil with manure is to cause a very rapid oxydation of the organic matter, and a very large quantity is converted into nitrates and nitrites and ammonia, but there is a limit to that, and it is impossible to ensure the safety of water where there is the possibility of contamination on a large scale with organic matters derived from sewage.

3178. If it passed through a sufficient depth of earth it would be deprived, would it not, of this matter?—The earth would be a great purifier, no doubt.

3181. Have you observed in a case where sewage has been discharged into a river that after running for three or four miles the effect of that sewage has been destroyed?—Yes, we have that in the case of the Southampton water supply; some sewage passes into the Itchen river, but it is quite destroyed by the time the water is distributed in Southampton, at least there is no detectable quantity.

3182. What is the distance?—The distance is six or eight miles. I could not undertake to say the distance in which water would purify itself in that way, but there is no doubt that it does purify itself, although in what distance, or what time, or under what precise circumstances I could not say.

3183. I presume that the sewage, probably by the action of the water and the atmosphere, would really be broken up into other elements of a less injurious character?—Yes, broken up into compounds of nitrogen and ammonia, nitrates and nitrites.

3184. You do not get rid of it, you have it in a different form?—Yes.

3185. And in a less objectionable form?—Yes, in a form I presume quite unobjectionable in a small quantity. A very large quantity might be irritant, but in a case in which they would be in water not very largely impregnated with sewage, I should think that they would not be hurtful.

3186. Do you think, taking the upper part of the Thames as a gathering area, that any injurious result from manuring or other washings into the river would by the course of such water down the Thames be somewhat neutralized?—I think that very likely it would be neutralized to a very considerable extent. That would rather depend upon the amount passing in; if any experiments could be made as to the amount of manuring and the number of acres that would furnish sewage matter, and the amount of sewage matter which would pass in, and the rapidity of the flow of the Thames at different parts of the year, and the volume at different times in the year, we should be able to form a better idea. It would be modified by a great many circumstances.

3187. But there would in your judgment be a process of purification going on?—Yes, it would be simply a question of degree.

3237. Do you think that in point of health the population of London generally suffer from any impurity in the existing water apart from any special case of cholera in the east of London?—I think that where the population of every town shows a considerable amount of diarrhœa, and also of typhoid fever, it makes one believe that there must be some impurity in the water at times, and the health of the population as regards those diseases of the intestines seems to be very much influenced by the purity or impurity of its water supply.

3245. If the subject had been considered one of vital importance by the medical profession generally, do not you think it would have been proposed that it should be scientifically investigated by some specially appointed body either of medical men or chemists?—We must remember with regard to the effect of different things upon the health of the community in this country that it has only been the subject of investigation for the last 30 years. Till we began to have statistics of deaths we had not learnt to know the relative prevalence of the several forms of disease, and it was impossible to form any opinion as to the condition under which the people were living. We may say that these questions are almost in their infancy.

Dr. Letheby, Medical Officer of Health to the Corporation of London:—

3879. Having regard to those waters, and the several tests which you have yourself made, what is your opinion generally of the water supplied to this metropolis?—My opinion is founded in the first place upon the actual analyses of the waters over a long period of time, monthly analyses; it is founded in the next place upon

an observation of the use of those waters very extensively, and I am bound to admit that there is no evidence whatsoever that those waters are in any way objectionable as a public supply. I am now speaking of the whole of the metropolitan waters.

3880. Notwithstanding the amount of organic impurity, that is your opinion?—The organic impurities are not large in the London waters. The loss by incineration, although a grain, is not regarded as a serious quantity, because the loss by incineration represents a great deal more than the organic impurities.

3891. When that interception takes place, will the water of the Thames in your judgment be greatly improved?—I do not think that it will be much improved. Not but that I am quite ready to admit that the discharge of sewage into such a river is a most improper thing, but considering the powerfully oxydizing influence of water upon sewage, the many agencies which are at work destroying it, the power of precipitation, the using of it up by vegetables and aquatic plants and by fish, and above all by the power of oxydization, I think that none of the sewage discharged into the Thames can at the present moment be discovered at Hampton, but nevertheless it is very possible that there may be a still further improvement of the Thames water by the adoption of these measures. Certainly there will be an improvement in this manner, that if the discharge of the sewage into the Thames were to go on increasing during the next 20 or 30 years, as it has been during the last 20 or 30, we should then probably have such an excess of sewage in the water of the Thames as would render it very unwholesome. But at the present moment I cannot perceive through the most refined chemical processes the existence of a particle of sewage in the water at Hampton where the Thames Companies take their supply.

3894. Have you at all ascertained in what length of time or distance polluted matter will be decomposed and transformed in its chemical qualities; for example, supposing we had the sewage from Richmond poured into the Thames, how far down the river would it be lost as sewage and broken up into other chemical elements?—I have made a very great number of chemical experiments to determine that. I have examined most of the rivers in England, and this is the conclusion that has been come to, not only in my mind but in the minds of all the engineers who have devoted their attention to this subject, that if ordinary sewage, containing we will say nearly 100 grains of solid matter per gallon, such as our London sewage, out of which probably something like 14 or 15 grains are organic, be mixed with twenty times its bulk of the ordinary river water and flows a dozen miles or so, there is not a particle of that sewage to be discovered by any chemical processes.

3898. Taking the case of the cholera disease and the discharges from the human body being mixed up with the sewage, do you consider that any germs of that disease would be carried down in water?—At the present moment we do not know what the germs of the disease are. If the germs of the disease be decomposing matter, then I do not think that they would exist in the water; but if the germs of the disease be living matter, then it is possible that they may exist in the water, but as nobody as far as I am informed can tell us what the germs of cholera are, it would be premature for me or anybody to theorize as to the probability or the possibility of their existing in the water.

3901. You are aware that it has been alleged that the main cause of the cholera in the east end of London was due to the water supply, do you entertain that opinion?—No, I entertain the opposite opinion. It was a matter of duty with me to investigate the whole of the circumstances connected with the East London supply. In the first place it was supplied to the hospital to which I am attached, in the next place it was supplied to the eastern division of the city, where, as officer of health, it was my duty to look well into the matter, and in the third place I had a general interest in it scientifically, apart from any official connexion with the subject, and I was very desirous to ascertain whether or not the water had been in any way concerned in the propagation of the disease. I therefore investigated it very fully.

3902. Are there two distinct waters supplied to that district?—Yes, but I will tell you this with regard to it, there is hardly anybody who can say, except in certain parts of the East London Company's district, whether the water had come from the reservoir at Old Ford or whether it had been received from the filter beds at the Lee, which is considered to be a good water, for the water was oscillating backwards and forwards in the mains in such a manner that the engineer himself had no knowledge what water was in any main at any particular time. But on the other hand there are places at which Old Ford water, and that water alone, is supplied, namely, Stamford Hill, Upper Clapton, Walthamstow, Woodford, Wanstead, Leytonstone, North Woolwich, and Silvertown, and excepting the two last-named places there was no cholera in any of them; there was a little in Silvertown towards the end of the epidemic, but the other places were free from it, and those were the only places where we actually knew that that water did go.

3904. Do you think the present supply of water to the London people is wholesome water?—I do, a thoroughly wholesome water.

Mr. Wanklyn, Professor of Chemistry at the London Institution, Finsbury, informs us that his attention has recently been directed to a new method of analyzing water for organic matters, and which he now considers sufficiently perfect to be worked. The preliminary experiments he has made show a larger quantity of free organic matter in the Thames water than Dr. Frankland's method, which he considers cannot detect all the nitrogenous matter. He says:—

. . I have to remark that the method of determining the organic matters which I use is a very simple one, and can be carried out in about three hours, and the determination is a perfectly direct one. I do not determine the total nitrogen in a water and then determine the nitrogen present as ammonia and nitric acid and give you the difference, but I determine directly the nitrogen present as organic matter, and that you will see is an important thing. The project of 10 years ago, (and it has been tried to be carried out, and it is admitted that it will be very difficult to carry it out,) was to give you the organic matter by a double process, giving you a difference; but my method is a direct one. I give you directly the nitrogen which is present in the organic matter.

5482. It has been stated in evidence before us that if you pour into water a volume of sewage equal to five per cent. of the volume of water into which it is cast, the water will so operate upon it in deodorizing and destroying and breaking up its elements into its primitive elements in fact, that it would no longer be sewage or possess any of its noxious qualities You apparently hold a contrary opinion?—This I am sure of; the urea in the sewage in such a water would be very readily broken up into ammonia and carbonic acid, and a little exposure would dispose of the urea, but the albumenoid matter in sewage is extremely persistent, and one of the results of the

whole investigation is this, that albumenoid matter is very persistent indeed, and you could not depend upon any treatment such as you have mentioned getting rid of the albumenoid matter.

5485. But will not certain changes take place, even in the albumenoid matters?—Yes, certainly; but the change is very slow, and it is very irregular. The change in urea is very rapid, so that you have to operate upon water recently taken in order to get your full quantity of urea.

Mr. Wanklyn subsequently sent us further testimony in a letter (Appendix A K), which is to the following effect:—

The result of a prolonged examination carried out by myself, Mr. Chapman, and Mr. Smith on the water supply of London, Manchester, Glasgow, and Edinburgh, last summer is the following:—

The water of the Thames at Hampton Court, where the companies draw their supply of water, is not very good, as it exists in the river; but after the filtration effected by *some* (but not all) of the companies, it becomes excellent, and in point of purity from organic nitrogenous matter is then fully equal to the water supplied to Manchester, Edinburgh, or Glasgow.

The water supplied by the New River Company is also very good.

Dr. Frankland, Professor of Chemistry in the Royal Institution and the Royal School of Mines:—

6222. What does your experience tell you is the effect of the quality of the present supply in London upon the health of the population generally?—I cannot of course trace any direct connexion between the present supply and the health of the metropolis; but I consider that water contaminated with sewage contains that which is noxious to human health. There is no process practicable upon a large scale by which that noxious material can be removed from water once so contaminated, and therefore I am of opinion that water which has once been contaminated by sewage or manure matter is thenceforth unsuitable for domestic use.

6224. Are we to understand that you are of opinion that this noxious matter exists in the water from analysis, or from knowing that sewage runs into the river from whence the companies draw their supply?—From both circumstances.

6225. Take the analysis first. What leads you to believe that there is that amount of sewage matter in the water which would be detrimental to health?—I find on analysis, as is shown in the table at page 17 of our report, that there is present in the waters delivered into London the following quantities of material, which may be regarded as the skeleton of the sewage which has been previously poured into the water; namely, of nitrogen, in the form of nitrates and nitrites, a mean quantity of ·192 part in 100,000 parts of water, that is, in the Thames water; in the river Lee water, as delivered by the New River Company, ·221 part in 100,000 parts; in the water delivered by the East London Company, which is also river Lee water, ·132 part; and in the chalk water delivered by the Kent Company, ·365 part in 100,000 parts. This skeleton, as I have called it, of previous sewage corresponds to the following quantities of average filtered London sewage, namely, in the Thames water to 1,751 parts of sewage in 100,000 parts of water; in the river Lee water, delivered by the New River Company, to 2,013 parts of such sewage; in the river Lee water, delivered by the East London Company, to 1,077 parts of such sewage; and in the chalk water delivered by the Kent Company, to 3,393 parts of such sewage. I must mention, however, that this chemical record is defective, especially in the summer months. It is defective in one direction, namely, that it gives the minimum amount of sewage only, with which the water has been contaminated; because in rivers we have vegetation in a state of activity during the spring and summer months, and also to some extent in autumn, and those aquatic vegetables remove this skeleton of the sewage to a greater or less extent from the water.

6226. You state that you have come to the conclusion that sewage has been the cause of the contamination of this water because you find a skeleton there in the form of nitrates and nitrites?—Yes, and also of ammonia, which I think I omitted to mention, but that is a very insignificant part of the skeleton.

6227. Is it possible that those nitrates and nitrites could be present in the water without its having been contaminated by sewage?—Could they be produced by some other cause than that of sewage?—They could be caused by manure thrown into the water, and by manure applied to the land.

6228. But are they attributable to nothing else?—To nothing else, I believe.

6233. With regard to the Kent water, we had some evidence yesterday to the effect that you must have been mistaken in finding traces of sewage in those chalk wells, the water being taken at a depth of 250 feet in the chalk, and the upper part of the wells themselves being lined; therefore the water must have filtered through the chalk, and there could be no trace of the skeleton of sewage. Is it your opinion that the skeleton of sewage as you describe it will find its way down to a depth of 250 feet, and that after filtration through gravel, and ultimately through the chalk, its presence will still be detected?—There cannot be a doubt about it, that this skeleton of which I speak, but which is a very different thing from the sewage itself, is present. I have never stated that the water which has filtered through the chalk in this way contains unaltered sewage; it is this inorganic skeleton of sewage that I find in water so filtered.

6234. Is it prejudicial to health?—It is not in a moderate quantity, such a quantity, for instance, as is contained in this chalk water of the Kent Company.

6235. With regard to the Kent water, the mean of the nitrates and nitrites according to the figures which you have just given us is ·365, and that amount in water in your opinion would not render it injurious to health?—That amount of nitrates I should say would have no deleterious effect upon health.

6236. It is scarcely necessary to say that in the case of the water delivered by the East London Company, which has ·132, the water of the New River Company, which has ·221, and the Thames water delivered by the Chelsea and Grand Junction and other companies, which has ·192, none of those four waters as at present supplied to London could have an injurious effect upon the health of the metropolis, in consequence of the presence of those nitrates which you say are the skeletons of previous sewage contamination?—Certainly not. Those nitrates would not in any case, I believe, be in the least prejudicial to health; but they reveal the fact that those waters have been previously contaminated with sewage, and, as I have already stated, there is no method which, with certainty, can be applied to water by which the noxious qualities of sewage can be effectually removed from it.

6237. But in all those four waters, as I understand you to say, after having had them analysed, you find the presence of those nitrates and nitrites, which shows that the waters had been in previous contamination with sewage?—Yes.

6238. But although they are in that state, you state, do you not, that there is nothing in them that could be injurious to health, and therefore the water is a wholesome water to drink?—I did not intend my statement to go so far as that. I meant only with reference to those nitrates in themselves, that the skeleton of the former sewage which is represented by nitrates and nitrites is not injurious to health; but we have no guarantee that other portions of that sewage may not have escaped the process of filtration through the chalk, and filtration through the land or over the land, and may be present in that water. Those substances are in too minute a quantity to be capable of detection by chemical analysis.

6239. Then your answer would apply as far as the nitrates would enable you to judge?—As far as the nitrates themselves are concerned that quantity of sewage matter which they represent is an innocuous form in the water.

6240. The presence of what other elements would lead you to a conclusion upon the quality of water as regards health?—In the first place when water is once contaminated with sewage, there is no process to which it is afterwards subjected which will effectually remove all that sewage contamination from the water. Filtration will not do it in certain cases, at all events. I have proved that the excrements of cholera patients cannot be filtered out of water; that after a degree of filtration which I believe is never attained by the water companies, and rarely attained perhaps by the passage over soils in irrigation, this water still remains opalescent, from the rice-water evacuations with which it has been mixed. The degree of danger which still remains in waters from different sources varies obviously according to the amount of filtration that the water undergoes. I would much rather drink the chalk water of the Kent Company, even if it had been contaminated to four times the extent of the Thames water, than I would drink the Thames water, because if I could have the assurance that none of that sewage or manure water had found its way into the wells through fissures in the chalk, the chalk water having passed through say 100 feet of chalk, would be very much better filtered than any water which finds its way to the Thames.

6241. When you speak of the difficulty of removing the effects of sewage contamination, does that difficulty apply to that which is held in mechanical suspension, or to that which is held in solution?—To that which is held in mechanical suspension. I believe that the noxious part in sewage is that which is held in mechanical suspension, not that held in solution.

6402. Still you are able to detect those globules?—No, they are beyond the reach of the chemist, and so far of the microscopist, I believe.

6242. Will no system of filtration remove it?—I would not say that it is impossible to remove it, but no system of filtration will secure its removal. There are only two processes by which it can be effectually removed; the one is by boiling for a long time, and the other is by distillation; and therefore it is that I say that, inasmuch as those two processes are impracticable on a large scale, in my opinion water that has once been contaminated by sewage ought not afterwards to be used for domestic purposes.

6244. Then are we to understand you to say that no amount of filtration would render those waters fitted for the supply of the metropolis?—As I have stated, no process of filtration that has hitherto been devised will remove choleraic dejections from water; and inasmuch as it is generally believed that the noxious matter of sewage exists there in the form of minute germs which are probably smaller than blood globules, I do not believe that even filtration through a considerable stratum of chalk could be relied upon to free the water perfectly from such germs.

6246. Do I correctly gather from your evidence that you think that no water that had passed over or through any cultivated district would be proper for the supply of the metropolis or other large towns?—I do think that that water is not safe for human consumption afterwards.

6247. That being your idea, would not it follow that no water could be supplied to the metropolis in a wholesome state from the Thames basin, because the whole of the Thames basin is as we all know very considerably cultivated?—Yes, I think it is very likely that that would be so; and inasmuch as the chalk water from shallow chalk wells exhibits this previous sewage contamination, I should infer that the springs feeding the Thames would also exhibit that contamination; but that does not necessarily follow, because it is stated that the deep chalk wells furnish a water free from nitrates and ammonia, or very nearly so, and consequently they are not so contaminated.

6248. Do you think then that there is a point below which the sewage matter would not get down?—At all events there is a point apparently below which the skeleton of the sewage no longer finds its way, it is either consumed by some living organisms and converted into other forms of matter, or it is absorbed by the strata themselves through which it passes. I have not myself analysed the waters of the deep chalk wells, but Mr. Dugald Campbell has done so, and he states that they are free from nitrates.

6278. Apart from the degree of hardness, in searching for water for the supply of a town, what should you be most careful in avoiding, having reference to the health of the population?—In avoiding a water which had ever been contaminated with sewage or manure matter.

6279. You stated, did you not, just now that the previous contamination, so far as it had ended in the formation of nitrates and nitrites, was of no importance?—That portion of the sewage which has been converted into nitrates and nitrites is of no importance.

6280. Therefore generally that might be left out of the question also?—Yes, so far as that itself is concerned.

6281. Apart from those two elements of consideration, what should you consider the substance to avoid?—In any water nitrogenous organic matter would be a substance to avoid.

6292. You conclude that it is very difficult to get rid of sewage matter by running water?—I do. That portion of it which remains undecomposed after its passage through the sewers oxydizes with extreme slowness. About four-fifths of the nitrogenous matter contained in fresh sewage, which has just been produced, as it enters the sewer is decomposed before the sewage, after a run of two or three miles, emerges into the river, and the remainder, I believe, as far as my experiments teach me, is decomposed with extreme slowness afterwards.

6296. Reverting to this particular question of the presence of organic nitrogen in those waters, what do you consider to be the effect upon water of the presence of organic nitrogen, whether derived from an animal or vegetable source?—As far as we know, the presence of organic nitrogen in the form of vegetable organic matter, such as peaty matter, is innocuous, unless contained in a considerable quantity in the water; but when contained in the water in the form of sewage matter it is believed to be noxious.

6297. Did I rightly understand you to say that you cannot distinguish in those cases whether it be derived from vegetable matter or from animal matter?—I have said that until recently it had been impossible to distinguish between the two, but that now I considered that the proportion between the carbon and the nitrogen in the two cases afforded a basis from which we could in many instances, decide.

6298. That is only an indirect method?—Yes, because the analysis itself gives no difference between the nitrogen from the two sources.

6328. It would seem that you could not very well refer the presence of nitrates and nitrites in all waters exclusively to previous sewage contamination. Without contesting that that may in many cases be so, are there other causes in operation which may have produced the same result?—There are, undoubtedly, causes which will produce a result of that kind to a certain extent. We have the presence of those materials, as I have already mentioned, in rain water, and it is conceivable that rain water falling upon a very dry sandy district, and evaporating there mostly from the surface, might leave those nitrates behind, and they might accumulate there to some extent from that source, and they may also be produced by the decay of purely vegetable matter. This strict analysis of water for nitrates is comparatively a new thing, and it is possible that we may find sources of those nitrates which we are at the present moment not aware of. But it is a remarkable circumstance that waters which it is well known cannot be contaminated by manure or by sewage never do contain those nitrates in a proportion bringing them near to the point of contamination.

6372. Then you do not accept the theory that sewage discharged at point A, and travelling down the river, is so oxydized as it passes a distance of six or seven miles, and is so entirely destroyed that its original elements are not to be found, but it is converted into some other substance or substances which are not detrimental to human health?—I believe that that is by no means a generally true proposition. I believe that under favourable circumstances, that is, when the water is warm, and there is a large volume of water, and the water is a good deal agitated in its course, that effect may be produced so far as regards the dead organic matter in the sewage, but not at all as regards the living germs that may be present in that sewage.

6382. And with regard to that which you do say is injurious [the unoxydized portion of sewage], you are hardly able to detect it?—Only rarely. Those waters are examined only on 12 days out of the 365, that is one point that must be taken into consideration. And I have only, in the case of the entire water supply, been able to get evidence which I consider anything like conclusive on this one occasion to which I have already alluded, namely, last month, on the 21st of January, when those waters contained this large proportion of organic nitrogen as compared with the organic carbon which they contained.

6383. That case to which you refer in January was quite exceptional, as I gather from your report of the 31st of January?—Yes; during the whole of the three years that I have examined these waters I have never found them in so bad a condition as upon that occasion, or in a condition approaching to that, but I may say that this condition of things having once set in lasted the greater part of a month.

6384. In this report of the 31st January you again repeat the words which I have just quoted; after giving the amount of sewage contamination in the water of the Chelsea Water Company, you say: "By gradual "oxydation, partly in the pores of the soil, partly in the Thames and its tributaries, and partly in the reser- "voirs, filters, and conduits of the company, this sewage contamination had been converted into comparatively "innocuous organic compounds before its delivery to consumers," and I think I find that almost word for word in all your weekly reports?—It is copied, in fact, from one to the other; it goes through the whole of them.

6385. Would that not rather lead the public to take it that your view was that this water was perfectly wholesome, or as nearly as possible perfectly wholesome?—I think it would, and that was the impression which I intended to convey, so long as I had not actually detected the presence of sewage matter unoxydized in the water; at all events I was very anxious not to convey the impression that analysis had discovered anything actually injurious in the water.

6386. Do you agree with those remarks of your friend Dr. Odling, which are separate from your report, "Although London is at present provided with an agreeable and in my opinion perfectly wholesome water," &c.?—No, I do not consider it a perfectly wholesome water, I did not at the time this was written, and that, I believe, caused my colleague to give a separate postscript to this report.

6389. In the month of January this year in your report you say: "The waters delivered in London during "the latter part of January by the Chelsea and especially by the Southwark and Lambeth companies, were "in such a muddy condition as to render them totally unfit for domestic use." On that point, filtration properly carried out would have met, would it not, that part of your objection as to the water being muddy?—Yes, certainly.

6390. From that we may gather, may we not, that your view would be that the question of the proper filtration of the waters is one of vital importance?—I think it is a very important point.

6391. You also state in your annual report: "The New River Company stands alone in the perfection of "its filtering apparatus. On no occasion during the past year has this company's water exhibited the slightest "turbidity, thus proving that perfect filtration is compatible with the largest daily supply furnished by any "one company in London." Do you see any reason why every company should not give out their water in the same perfect state that you here describe the New River Company does?—I see no reason whatever why the other companies should not.

6392. And do you consider that it would be a desirable thing in case of necessity that such a delivery of water in a pure state should be enforced by legislative enactment?—I do; in fact, it is so enforced at the present moment.

6426. What should you consider the essential conditions of a good drinking water?—The essential conditions of a good drinking water I should take to be, first, coolness and aëration; secondly, freedom from animal organic matter of all kinds; thirdly, that it should never have been contaminated by sewage or manure in any form; and, fourthly, that it should be soft water, not over five degrees in hardness.

Dr. Odling, Professor of Chemistry at the Royal Institution and at St. Bartholomew's Hospital:—

6447. You have examined the Thames water from time to time, have you not?—I have examined it fully.

6448. Have you found in those examinations of the Thames water the presence of sewage not decomposed?—I have not.

6451. Has your attention been directed to the important principle of the self-purifying process which is going on in rivers running at a given velocity?—Yes, it has. There may be great differences of opinion as to the degree to which that self-purification takes place, but that it does take place to a very considerable extent I think is undeniable.

6452. You will understand my question as not referring to sluggish waters, but to rivers where the body of water would become exposed to the action of the atmosphere as it passes along?—You may see in many rivers, even sluggish rivers, having sewage discharged into them, that for a mile or two the appearance of the river is affected by the sewage, but beyond a certain distance there is no recognizable effect at all, the weeds are perfectly clean and perfectly healthy.

6453. Do you know Leicester at all?—Yes.

6454. Do you know the condition of the river there?—Yes, I do.

6455. Near to the town it was in a very bad condition, and the water quite black, was it not, when you saw it, from the refuse of manufactories and the discharge of sewage?—Yes.

6456. Did you observe the condition of that river three miles from the town?—Yes, and from its appearance you could not tell that it had been contaminated, it was running clear, with fish swimming in it, and the weeds were clean.

6457. And that simply from the process of self-purification?—Quite so.

6459. You have not detected any of the skeleton forms which Dr. Frankland has given utterance to?—That is a point on which I am a little at issue with Dr. Frankland with regard to the interpretation to be put upon the presence of nitrates in water. It is admitted that the presence of nitrates says nothing for the present condition of water at all, and I rather dispute that it says anything very important for its history. There is no doubt that a very large quantity of sewage, or the equivalent of sewage, is discharged into the river Thames above the source of the present water supply, and I do not mean to say that Dr. Frankland exaggerates that proportion at all—I do not know whether he does or does not—but I contend that the estimation of the nitrates in a water does not give any ground on which to estimate its proportion of sewage.

6460. But when found are they in your judgment injurious to the water?—In such quantities as are found in the river supply of London they are, in my opinion, perfectly innocuous.

6461. Still less, I suppose, if found in chalk?—Yes, quite innocuous if found in chalk.

6462. Is it your opinion that those which have been found in chalk are due to sewage?—It is a point upon which there is no positive evidence, but I am inclined to think that it is not so, for we find them distributed so irregularly. For instance, the deep well water at Trafalgar Square, and the deep well water from the greensand, and lower chalk all over London, is nearly free from nitrates and nitrites; whereas the water of equally deep wells elsewhere in the chalk is found to contain very considerable quantities of nitrates. The deep well water from nearly all formations has been found to contain nitrates. Then, moreover, a proportion of the nitrates which the sewage itself undoubtedly does furnish, in one case is destroyed and in another case is not; and so far as the history of the water is concerned, in the one case where the nitrates are destroyed, that water may show but a very small amount of previous sewage contamination, whereas it might have had a much larger amount than the other.

6463. Apart from the question of sewage, is it your opinion that the condition of the Thames basin is such as to render it an unfit gathering ground of water for domestic purposes?—I do not think it at all unfit.

6467. Do you agree with Dr. Frankland, that supposing a system of perfect filtration were adopted (and he appears to consider that the New River Company has a perfect system of filtration), and if all the companies were to use the same process, we should have a water perfectly wholesome for domestic purposes?—Certainly I do.

6472. The presence of nitrates, if not in excess, is a comparatively unimportant element?—It is an unimportant element as to its state, and I believe it to be in many cases an unimportant element as to its history.

6473. You have heard the questions that were put to Dr. Frankland with regard to the probable origin of nitrates. Are you of opinion that their origin may be traced to several sources?—I am quite of that opinion.

6474. With regard to the presence of nitrates in the deep chalk wells of the Kent Company that have been referred to, they show a quantity of nitrates present as large or larger as in the Thames water; but it does not follow, does it, that they are necessarily derived from the same source?—Certainly not.

6477. What do you consider to be an essential quality of good water for drinking purposes?—It should be bright, colourless, and brisk, and it should not contain any considerable amount of nitrogenous matter.

6479. Do you think that there is no risk in using for drinking purposes waters which are derived from rivers the population on the banks of which is constantly increasing?—Of course it is conceivable that the amount of impurity discharged into the river may exceed the power of the river to purify itself, or approximate so nearly to that power as to leave a balance that it would not be safe to rely upon.

This gentleman also makes the following remarks in his report (Appendix D.) on the analysis on the Welsh and Cumberland waters:—

Although London is at present provided with an agreeable, and in my opinion perfectly wholesome water, still it is evident that for general town supply a soft water such as that of Wales or Cumberland is upon the whole more suitable than a somewhat hard water such as that of the Thames and Lee; and, further, that a water which neither contains nor has received sewage impurity is at any rate preferable to a water which certainly has received, even though it does not actually contain any such impurity.

Sir Benjamin Brodie, Professor of Chemistry in the University of Oxford:—

6986. It has been stated in evidence before this Commission that in the case of sewage discharged at Windsor into the river, and flowing down the stream six or seven miles, or rather more, at that point they have failed to detect the presence of the sewage, that from oxydization or the breaking up of the elements it is in such a condition that they have found nothing which in the judgment of the witness would be prejudicial to human health. Have you made any observation bearing upon that point?—I have not myself made any observations on that point, and indeed I do not know how such an examination could be satisfactorily conducted.

6988. Have you formed any opinion as to the probable effect of the flow of seven miles upon water contaminated with sewage, whether at the end of that distance or any other distance it would be fit for human use, or could be considered to be a safe water?—The sewage would be during its course to a certain extent oxydized and destroyed, and resolved into other compounds, but how shall we say that all the sewage is resolved and destroyed so that the water should be safe. To do that we must be able to apply some extremely sensitive test to the water which would enable us to ascertain the presence or the absence of sewage in it, and I want to know what the test is which we are so to apply. There are causes operating, as we all know, to destroy the sewage which, to a certain extent, will effect that end, but the question, as I understand it, is whether those causes are really adequate to destroy the sewage not partially, but absolutely and entirely, during a given course of the river.

6991. You have been supplied with a copy of the medical evidence which has been laid before the Commission, and no doubt you have observed that we have evidence on both sides, one party alleging that water impregnated with sewage will be purified by the action of the air and oxydization in its course a few miles down the river, but, on the contrary, Dr. Frankland states very distinctly, that water once contaminated with sewage is unfit for human use, and that you will still find what he calls the skeleton of sewage present,

although it may have travelled 100 miles and been exposed to filtration?—I think what is asserted by Dr. Frankland is true, that there are no known causes in operation on which we can adequately rely to remove the sewage from the water. That causes are in operation which partially remove that sewage and diminish its injurious effects is true, but the question is whether those causes, as I said before, are adequate to produce a complete result; that is to say, whether they will take out of the water all the injurious matter which is contained in it, so as to render it fit for drinking. I do not think it possible, in the present state of our knowledge, to pronounce an absolute opinion upon that point. But if you ask whether it is wise to drink water into which you have put sewage, knowing that you have no positive means of getting that sewage out of it, that is a question which anyone can answer for himself, assuming always the injurious character of sewage. I am not now pronouncing any opinion upon that point, or saying in what degree sewage is injurious; that does not appear to me to be a chemical question. I think that is a question of very great importance, but which is much more likely to be solved by other agencies than by chemical experiments. Medical statistics will tell you more about the injurious or non-injurious character of sewage water than any analysis would do. It does not seem to me that we have, as I before said, any accurate chemical measure of the sewage in the water, at all events I do not know what that measure is. I have read the evidence which has been given by Dr. Frankland and one or two other witnesses also before this Commission, but I still hold to my opinion that we have no accurate measure of the sewage matter in the water, or even of the previous sewage in the water.

7004. In all those analyses a certain value is ascribed to previous contamination, as determined by the presence of nitrates and nitrites in the water; will you give your opinion whether the presence of nitrates and nitrites is to be ascribed to that one source alone, or may it be ascribed to several sources?—I think the probability would be that the presence of a large quantity of nitrates and nitrites would indicate the previous presence of organic matter in the water; but I do not know that you could take that nitrogen, in the shape of nitrates, as an absolute measure of that organic matter, which is a different thing.

7006. But is it not possible that in many cases such salts may be derived from other sources than that of previous sewage contamination, using that term in its common acceptation; may they not arise from other matters in the soil, and therefore is their presence a fair indication of previons sewage contamination?—I believe that nitrates may occur from other causes, but I cannot speak from positive experience.

7009. Dr. Franklin considers that this organic nitrogen in the London water is of a different value from that in the lake waters, because the proportion of organic carbon to the nitrogen in the waters is different?—Yes. This appears to me a very important fact, and may really indicate that the organic matter in the water had, in two cases, a different origin.

7011. You think that the tests of the greatest delicacy are yet insufficient to determine the point at which sewage ceases to be present?—I may take a case which really is an absolutely analogous case to the case of water, namely, the case of the atmosphere. You may look at the atmosphere as really a great ocean. Gases from drains are being discharged into this gaseous ocean just as the water from the drains is going into the river. Those gases are so diluted when they get into the atmosphere that chemical analysis is absolutely mpotent to reveal their presence in any given portion of the atmosphere. But nobody can doubt the njurious effect, under certain conditions, of the gases and other organic matters present in the atmosphere. Take the case of the Westminster drain, the opening of which is known to have occasioned a great outbreak of fever here. You say that you would not live in a house next it, nor at the end of the street, nor at the end of the next street; but where should you begin to live so as to be safe from the effluvia of that drain? We cannot answer that question. I suppose if I get to Oxford I am safe from that drain, but we have no chemical tests,—because that really is the only point at issue,—to apply to the air to say whether or not it contains injurious or poisonous organic matter from the drain. In the atmosphere just as in the water there are constant processes going on with great efficiency to destroy those noxious gases; and a person would argue, just as is done in the case of water, that you have sulphurous acid from the chimneys of London, you have the oxygen of the atmosphere, you have nitric acid, you have ozone in the atmosphere. All these agents, happily for us, are at work destroying those noxious gases from the drains and sewers and other places. But when is their work completely done? That is what we do not know. Another most important thing is this, that really there is no reason whatever to believe that the injurious character, either of sewage or of the gases from a drain, depends, fundamentally, upon the quantity of that sewage or of that gas; in all probability it far more depends upon the quality of the sewage, namely, what it consists of. Now what is the nature of the poisonous matter in the atmosphere or in the sewage? We do not know that at all. Therefore how can you possibly say when that poisonous matter is got rid of from the water or from the air. It is a question that with the means at our disposal it is absolutely impossible to answer; and I say as I said before, that I think you have a much better chance of getting at these relations through accurate statistics properly applied, than you have through chemical analysis, because chemical analysis is one of the poorest things possible to reach those delicate quantities. You cannot get at those small quantities at all. Chemical analysis must be limited by our power of weighing and measuring; we can only do those two things. We can weigh and we can measure, and we can do that with a certain accuracy, and there we stop; but that accuracy is not capable of being multiplied *ad infinitum*. It may go on to a certain point, but we cannot go beyond that point. I think that it is impossible absolutely to answer those questions, for we have not the data; but the question arises, as I said before, whether a prudent person likes to drink water which contains a certain quantity of nitrates and nitrites, or that when analysed is found to contain a certain quantity of organic carbon and nitrogen, water into which you have deliberately put cartloads of sewage at some time or other in its course.

7014. Oxydization is constantly going on in the soil and in the river, and therefore there must be some point at whichcthe perfect destruction or oxydization of this animal matter must take place?—What I think is muh more important still is another point, namely, the great dilution of the material, and I should rely upon the dilution quite as much and more than upon the destruction of the injurious matter. Supposing the sewage of a large town such as Oxford pouring into the river, there are numerous feeders and tributary streams to the river which effectually dilute the sewage. The sewage is gradually getting proportionately less and less, and therefore its noxious character diminishes and ultimately disappears.

7028. It is a perfectly possible and conceivable thing that a very minute proportion indeed of sewage in the water might be most extremely injurious to health. I say that partly from general experience, and partly because I have had occasion myself very frequently to observe the vast importance in chemical changes of what people so frequently pass by as inappreciable quantities of matter. Indeed, I have occasion to see more and more every day that minute portions of matter, which previously were not suspected at all to exist, exercise important influences on chemical transformations.

7041. If water is supplied to a town from a river which in a part of its course has received previous sewage contamination, and if that water is used on a large scale by that town and produces no ill results,

and chemical analysis fails to detect anything unusual in its character, is it not a fair presumption that such water is wholesome and good water for the use of a town supply?—If it be used without injury to the inhabitants, really chemical analysis is altogether superfluous. But the question is whether it can be always and permanently so used. That seems to me to be the real point at issue. We should have found out long ago the injurious effects even of small quantities of sewage if the sewage were always injurious; but that is not asserted. It is only supposed that, under certain exceptional conditions, even sewage may become very injurious. The injurious character of a water impregnated with sewage matter might not be discovered for years. You might long go on using it, for years, and it might not be discovered, and yet you might have some outbreak of disease in the place which, nevertheless, might be connected with the use of that sewage water.

7043. You consider then that with regard to the effect of water upon the health of the inhabitants, it is rather a question for the medical observer than for chemical analysis?—I really think so. I think that chemical analysis is not yet sufficiently advanced (whether it ever will be I do not know) to pronounce a decision upon the matter, and that you have a better chance of getting at the real connexion between the injurious matters in the water and diseases generated by those matters through statistical observations carried on upon a large scale than through chemical analysis. Statistics elicit relations of cause and effect on which you cannot deliberately experiment.

Dr. Miller, Professor of Chemistry in King's College, London:—

7066. What was [in 1859] the state of the water at that part of the river above Teddington lock where the water companies are now taking their supply?—Above Teddington lock the water was very good, even at that time when there was but a scanty supply of water in the river.

7068. Did you detect in the water taken from above Teddington lock the presence of sewage?—There was organic matter, but I should not have called it sewage.

7069. Did you then form an opinion that it was traceable to sewage or partially traceable to sewage or to some other cause?—I did not specially determine whether it was sewage matter or what the origin of the organic matter was.

7070. Would there be a difficulty in determining whether the nitrates were due to one source or partly to one source and partly to another; for instance, the drainage of land, the manuring of farms upon the watershed, and the washing of the remains of the sewage into the river?—I do not think there is any means of determining what proportion of the nitrates is due to the natural supply from the chalk springs, and what is due to the oxydized sewage. In fact there is no means of determining that. They exist exactly in the same condition in the water, and therefore a proportion of the nitrates may be due partially to the one cause and partially to the other, the proportions varying with accidental circumstances.

7072. You have seen the evidence of Dr. Frankland in which he refers to the presence of sewage in the form of skeleton; if the view which he takes is a correct one would the presence of that skeleton be injurious to health do you think?—I understand that merely as a figurative expression showing the existence of nitrates and ammonia in the water. Neither of those things in themselves in small quantities is in the least degree injurious. I am speaking now simply of them after they have been completely converted into that condition of nitrates or of ammonia.

7074. You are aware Dr. Frankland takes a very strong view of the presence of that skeleton of sewage, because, in referring to certain wells used by the Kent Waterworks Company, where the water is pumped from a depth of 250 feet through the chalk, notwithstanding the filtration at that depth he still detects the presence of those skeletons of sewage?—That is to say, he finds nitric acid or nitrates, and he assumes what I think he is not justified in assuming, namely, that those nitrates are the result of the putrefaction, or rather of the decomposition of sewage matter. No doubt they are formed by that operation in a great number of cases, but to say that they are always formed so would be, I think, far beyond what the facts warrant.

7077. I do not deny or doubt that in a great number of cases the presence of nitrates does indicate the previous existence of some organic contamination. The only difference between Dr. Frankland's view and mine is this, that he assumes, apparently in all cases, at least if I read his evidence aright, that nitrates invariably point to previous sewage contamination. I think that that is not justified by other observations. The experiments of M. Boussingault and others show distinctly that the formation of nitrates does occur where there can be no suspicion of previous sewage contamination.

7082. Are you of opinion that water once contaminated with sewage can never be considered a safe water afterwards?—I think experience is quite against that. I think it is safe; evidence shows that it is safe in the majority of instances. There may be cases in which danger is produced.

7088. Have you made any experiments upon the power of water, in a given course, to oxydize organic matter?—I ascertained a remarkable result in the course of the summer of 1859 upon the river. I took specimens of the water at Kingston, at Hammersmith, at Somerset House, at Greenwich, at Woolwich, and at Erith on the same day, and I examined the quantity of oxygen which the water contained at all those different points. I found that the quantity of oxygen at Kingston was the ordinary or normal proportion; at Somerset House it was much diminished; at Greenwich the whole of the oxygen had disappeared; at Woolwich it was much in the same condition, and at Erith the water was very much improved, showing that this diminution of oxygen had been produced by its action upon the water contaminated with the sewage of the London district, and that as it passed lower down the oxygen was again absorbed from the air, and again it became diluted with a large volume of water from below, from other sources, the Lee, the Ravensbourne, and other tributaries, and in this manner the water had again become oxydized. I look upon this as a direct proof of the effect of oxygen in destroying those organic contaminations which are thrown into the river.

7099. You consider, do you not, that in small quantities the presence of such nitrates would be innocuous?—Yes; the presence of large proportions of nitrates would no doubt indicate communication with some source of animal refuse. Well waters in towns very commonly contain large quantities of nitrates, especially in the neighbourhood of graveyards.

7100. But they contain very unusual quantities?—Yes, quite large quantities; sometimes I have seen as much as 20 grains in a gallon.

7101. Have you had occasion to analyse any waters which you have reason to believe are removed from the possibility of previous sewage contamination, and yet found nitrates present in them?—Yes, the waters from Watford, which come from chalk wells, where there can be no suspicion of previous sewage contamination, always contain nitrates.

7104. Organic nitrogen, I presume, is the substance the presence of which in any excessive quantity is to be avoided?—The presence of organic nitrogen may be derived from substances which are quite harmless,

or it may be derived from substances which are very injurious, and we have no means of distinguishing between the two. Nitrogen is always present in such combination, not as nitrates, and not as ammonia; but the presence of nitrates is always a suspicious circumstance in water, and the greater the quantity of nitrates the more suspicious is the nature of the water and the more reluctant one would be to use such a water as a source of supply.

Dr. Robert Angus Smith, Government Inspector of Alkali Works :—

7184. Have you directed your attention to the quality of waters supplied for domestic purposes?—Yes, I have.

7185. Have you made any analyses which you can refer to as giving information on that point?—I have made a great many analyses, but I have not brought any with me. I only intended to speak here on general principles, and especially about the organic matter which seems to have raised a discussion of more importance than, I think, any other subject in connexion with water.

7186. Will you be good enough to state your views upon the subject?—Some time ago, in studying the organic matter of water, I divided it into many parts. It had been common in analyses of water to write down the organic matter as if it had some special quality. Afterwards, however, I found it necessary to consider organic matter as a very complex substance, and instead of putting it down under one head I have put it down under at least eight heads, and some of those heads have subdivisions. The first head which I think it would be worth attending to is organic matter, which is putrefied. This would include the gases and vapours arising from putrefaction, and this is the thing which strikes one more especially on coming in contact with water which is impure; for example, in drinking it would be offensive to the smell, and generally it will give those characteristics that were found in the Thames some two or three years ago. I examine this part by means of permanganate of potash. It is very readily done.

7187. As I understand it, although you break up that which is usually designated organic matter into eight parts, still those eight parts form but one matter that is called organic?—It is so; it is one of the great divisions.

7188. None of those eight parts would have reference to anything except the original matter which is called usually by chemists organic matter?—No; but they will be as different in their properties as, I may say, organic or inorganic matter are—so widely apart are they in quality. It is difficult for one to give exactly all the particulars, but I will first say how I examine the gases of putrefaction. I use generally permanganate of potash for that purpose; that was the plan adopted by Professor Vorckhammer, of Copenhagen, some years ago, for organic matter generally, and it has been adopted by several chemists since, and rejected by several others as of no value. I find that it is of value. . . . . I may say what I found in the Thames. Above Reading very little impurity was found in the Thames, but below Reading it was very marked indeed, and it never disappeared in any part below Reading.

7198. For what distance down?—Any part. I went down to London Bridge, and it was visible in any part below Reading.

7199. Did you detect the presence of sewage from every sample that you took below Reading to London Bridge?—Yes, what I believe to be caused by sewage; it was organic matter, which in its decomposition showed a great deal of animalcular life, and which I believe to indicate so much organic matter of a very active kind, probably dangerous.

7200. Supposing there had been no source of contamination below Reading, would you then have been able to detect the presence of sewage in the river, because, as you are aware, down the river there are fresh sources of contamination going on?—Yes, I think there would have been a little. I may say that above Oxford I considered the water extremely pure, but below Oxford and I might say down to Pangbourne, it was, perhaps, a little less pure, but very little. I considered at that time that it was not proper to take water from any source below Pangbourne at any rate. Perhaps I might be inclined to go higher now, but that was my view at the time when I examined the water for the Metropolitan Sanitary Commission, which is now 20 years ago nearly.

7201. Are you of opinion that a water once affected with sewage contamination is never after a safe water for domestic purposes?—I think it may be quite safe. It is so in some cases, in others not.

7202. Under what condition?—Supposing it were very impure indeed, the first thing that would occur would be putrefaction; that gives out a number of nauseous gases, and the most prominent to the senses is, perhaps, sulphuretted hydrogen. After the putrefaction had finished a great deal of the organic matter would be removed. If any remained, and it were exposed to oxydation nitrates would be formed. Those nitrates are, I consider, so far offensive as they indicate very bad company, but in small quantities I am not aware that they can be considered hurtful. On the contrary, to some extent they are a very valuable accompaniment of organic matter. They themselves are disinfectant and prevent processes going forward which would be unpleasant. . . . . If the germs pass into rivers we do not know how far they may be carried; on the other hand, we do not know that they ever can be carried in pure water; the dissolved oxygen may destroy them, as it unquestionably does putrescent matters. A positive proof of their transmission in otherwise pure water is wanting. We might ask if a cholera germ in the water at Oxford would produce disease in London; and we might answer by asking if one cholera germ passing into the air at Woolwich would produce disease in Pimlico. This we do not know; but it seems probable that disease cannot be carried far by pure air or by water with much oxygen in it, which is equal to pure air. We are informed that the atmosphere is full of germs; but the evidence seems to be that it requires an unusual excess to attack us successfully. It seems to be a question of quantity. Still there is the sentiment remaining; we do not like that any sewage should enter the water that we drink. I am disposed to think it well to listen to this sentiment, so far as large towns are concerned, although even then we must remember distance and quantity; but so far as villages and ordinary agricultural drainage is concerned, I am not aware of any experiments showing sufficient room for fear.

7242. Are we to understand you that you would be guided as to the objectionable quantity of organic matter in water rather by the results showing the development of animalculæ than by the results of chemical analysis?—I think that one of the most important experiments that can be made, although I would not neglect the others. I have seen some very striking instances indeed, in which an enormous number of animalcules have been found in water which at first appeared perfectly pure, and quite a contrary result has taken place in water which I thought to be inferior.

7244. I understand you also to say that if you give the water a sufficient length of flow this organic matter will be oxydized more or less completely?—Yes, that is always the case. It is a question of length of flow, or length of storage, or depth of drainage; those are the three most important points.

7247. The nitrates are what I have called old organic matter. There is no doubt that by the oxydation of nitrogen compounds nitric acid is formed. I imitated this process long ago, using chiefly yeast, and so produced nitrates from yeast or vegetable matter. The nitrate comes from animal and vegetable albumenoids indifferently. When estimating the London sewage we may readily refer most, if not all of it, to animal matter or sewage. In the river above London some of the nitrates come I do not doubt from vegetable matter. I have not estimated how much comes from one and how much from the others. I am inclined to think that nitrates coming down may be divided into the animal and vegetable nitrates, and measured. Albumen, &c., would produce nitrates without being used by animals. When nitrates are caused by matter from animals there is always a corresponding amount of common salt. Men take from 200 to 300 grains at least of common salt every day, and it is given out every day. This is the most unchangeable accompaniment of sewage.

7253. In most cases where there is danger to be apprehended from the presence of nitrates have you not been able to detect the presence of chlorides?—Always. Whenever chlorine is high in the water it is necessary to look for nitrates derived from sewage, and, as a rule, it is so constant that there is scarcely any exception. When we find much more than the average quantity of chlorine in a well water, nitrates are found also, and if the water in a district is pretty well known, that is to say, if the amount of chlorine in water from any district is pretty well known, and a specimen of that water should indicate rather more chlorides than usual, you may conclude with almost certainty that it is from sewage.

Messrs. Letheby, Odling, and Abel, in the analyses for the metropolitan water companies, given in Appendix AH, add the following remarks:—

With reference to the second part of your letter, in which you request us to report on the system pursued by Dr. Frankland in obtaining and recording his analytical results, we have to offer the following few remarks.

Without discussing the question of the general applicability of Dr. Frankland's method of water analysis, which are at present we believe almost exclusively employed by him, we must express our dissent from one of the inferences which he founds upon his analytical results. In particular, we contend that the proportion of nitrogen discovered in water, in the forms of nitric acid, ammonia, &c., is not a trustworthy measure of the extent to which that water has, at some time or other, been contaminated by sewage, inasmuch as the nitrogen compounds existing in a water may, on the one hand, greatly exceed, and, on the other, equally fall short of those which would be furnished by the addition to the water of a given proportion of sewage (using the latter term in the broad sense in which it has been applied by Dr. Frankland), thus, for example, we cannot accept as a correct representation of the relative condition of the East London water (from the river Lee), and that supplied by the Kent Company from deep wells in the chalk, the statement of Dr. Frankland in the Registrar General's Weekly Return for May last (No. 22, page 179) that the former contains 0 parts of previous sewage contamination (estimated) in 100,000 parts of water, while the latter exhibits 3,540 parts of previous sewage contamination in the same amount of water.

It scarcely need be pointed out by us, that the apparently higher results which Dr. Frankland's published analyses record, as to the solid constituents generally existing in water, when compared with those given in the reports of other analyses, are simply ascribable to the circumstance that they are calculated on 100,000 parts of water instead of on the imperial gallon of 70,000 parts, as is the general custom.

In conclusion, we have to express our opinion that no useful results, but the reverse, can be attained by expressing in large multiples, as in tons (see Registrar General's weekly returns), the small proportions of mineral or other constituents, which analysis discovers in potable waters, and by designating as *impurities* perfectly harmless substances which exist, in varying proportions, as normal constituents of nearly all natural waters.

Engineers and others.

185. The Rev. J. C. Clutterbuck:—

1805. You are well acquainted, are you not, with the surface condition of the watershed of the Thames for some hundred miles up?—Yes, all the way.

1806. Is it highly cultivated?—It is highly cultivated, decidedly.

1807. And what, in your judgment, would be the effect upon the water in the rainfall passing through a soil so cultivated?—With reference to the chalk surface, I do not conceive that there would be any great amount of effect produced by cultivation on the water percolating that part of the country, because it would sink through so very much soil.

1810. Looking at that general condition of the surface and at its geological formation, is there in your judgment any objection to that gathering area for water for the purposes of domestic use?—No, I think not, I cannot say that I see any.

Mr. Hawksley:—

2553. The great complaint of London water at present is not the quality of the water itself so much as the polluted district through which it passes?—That, I think, there is the greatest possible amount of misconception upon; there is a great deal of prejudice, not unnatural at all, but still amounting to prejudice, upon that question. I believe, in fact I know, that the water of the Thames at Hampton is very excellent water, very pure, very free from organic matter, and that what little organic matter it does contain is of a very innoxious character.

5076. What quantity of water, as compared with the volume of sewage, is necessary for the purpose of breaking up into its original elements the sewage which has been discharged into it?—Generally about 20 to 1. If the water flows rapidly and is very much disturbed, so as to be continually receiving fresh oxygen, a smaller quantity, even 12 to 1, will effect the process; if it proceeds very tardily it may take a little more; but usually 20 to 1 is perfectly abundant. I could give you very remarkable instances. Take Sheffield: nothing can be fouler probably than the state of the water at Sheffield, whereas if you go down to Doncaster the water is supplied by the waterworks, and is actually drunk in the town. I do not, however, say that it is a desirable thing.

5077. How many miles is Doncaster below Sheffield?—About 20 miles.

5078. Is it a rapid running stream?—No, it is not rapid in summer. In point of fact it is controlled by the weirs set up for the navigation. But take the river Irwell leaving Manchester, receiving the Irk, the Matlock, and all the refuse of the manufacturing population for a great many miles; when it travels down only eight or nine miles to Warrington it is perfectly changed, it ceases, or nearly ceases, in that short distance to be an

offensive river. I do not say that it has become all that it ought to be by any means, because the distance is not sufficient, and the flow is not rapid enough. The river is canalized, which prevents its flowing with all the rapidity it ought to have.

5079. You remember, do you not, the original condition of the river at Leicester after receiving all the sewage of the town into it?—Yes, perfectly well. I happened to be the engineer at Loughborough and also at Leicester. I made the waterworks at Leicester, and I advised the sewage works at Loughborough, and I also was called in to design waterworks for Loughborough, and I had on those occasions to take particular notice of the state of the river at all times, both at Leicester and at Loughborough, Loughborough being about 12 miles below Leicester. At Leicester the water was as black as this ink. I do not mean to say that it was absolutely so thick, but looking at it in a mass it was as black as ink—nothing would live in it, and the smell was abominable,—but by the time it got to Loughborough it was entirely restored to its pristine condition. You could stand on the bridge there and see the fish swimming amongst the beautiful reedy and other plants growing in the water just as in the purest stream. You could see every pebble at the bottom. That is an instance of the effect of oxydization.

5080. The water has symptoms of returning purity, has it not, within four miles of Leicester?—Yes, but not to the same extent as at Loughborough. The water was perceptibly impure at the driest period of the year down as far as Barrow. It could be just perceived there, but at Loughborough it was perfectly restored.

5083. Having regard to the capacity of the Thames watershed to yield a sufficient supply for the metropolis, (and when this system or purification is completed, whether for the sake of removing prejudice or any other purpose, to get rid of filth at all events the water must be improved,) you are of opinion that there is no necessity to seek a supply of water from a distance from the metropolis?—Certainly not. You have very fine water surrounding London in all directions, and it only wants utilizing.

Mr. Beardmore, Engineer to the River Lee:—

3329. What is your opinion as to the quality of the water supplied from those sources for the uses of the public generally for sanitary and domestic purposes?—I think that with proper arrangement of reservoirs the quality may be faultless, always excepting the carbonate of lime, which I regret to see published every week as so many grains of impurity, being merely a solution of pure chalk in the water. It is called in the papers impurity, but setting aside that carbonate of lime you will never get a purer water. In fact the New River is as pure as Loch Katrine now very generally, and with reasonable arrangements you may have the water still purer.

Mr. Leach, Engineer to the Thames Conservancy Board:—

4289. It would of course greatly improve the river if that sewage and other contaminating matter were diverted?—It would improve the condition of the river, but I think that the contamination has been very much exaggerated. In those country towns there is no regular system of sewage generally. The majority of the houses drain into cesspools; and really there is no very large outfall in any case except at Windsor; there a more perfect system of drainage has been carried out, and there is a most offensive outfall.

4290. Still there must be a very large amount of ammonia flowing into the river notwithstanding the cesspools, because of the overflow which you must necessarily catch in the river. A cesspool is very soon filled, and though not filled with solid excreta still there is an overflow, and that must find its way into the river ultimately?—The ground absorbs a good deal of that. I have noticed the outfalls of some of the larger towns, such as Abingdon and Wallingford, and although they are unquestionably offensive, still there is not that volume which would be the case with a similar population in London.

4291. Is the volume of water in the river sufficient to deodorize it?—Yes, it very soon loses any contamination.

4292. Take Windsor for example, where there is a discharge of a considerable amount of sewage out of their drains, have you observed the condition of the river at the point of discharge and also a few miles down?—Yes, I have.

4293. How soon in your observation is the effect of sewage destroyed by its flow and admixture with the water?—At Windsor it is discharged into a most unfavourable point in the river, where there is little or no stream at ordinary times. At times of flood of course there is more stream, but usually there is very little stream there, and the matter which is passed out of the drain floats about in the river there to a very great and very disgusting extent.

4294. Is there an eddy there, or what?—No, there is a weir just immediately below, which deadens the stream sufficiently to deprive it of the force required to take what is floating away. Two miles or even a mile below that I could see no traces whatever of the sewage.

4295. Was it all broken up and destroyed?—Yes, and taken by fish, and so on.

4296. Is it the habit of fish to take up matters of that kind?—Yes, you generally see persons fishing close to the outlet of a drain. I think that the operation of the Act of 1866, which prohibits the discharge of sewage into the river, will have a very beneficial effect. If some such provision had not been passed I can quite understand that as the system of waterclosets was extended and a more perfect system of drainage was carried out, the river would rapidly become much more contaminated; but the powers contained in that Act will, I hope, put an effectual stop to the pollution of the river.

Mr. Simpson:—

4625. With regard to the effect of the London water, which your companies supply, upon the health of the population, do you consider it an unwholesome water?—No, decidedly not. I believe the water to be as wholesome as any water that we can obtain.

4627. Are we to understand that you have heard nothing or seen any returns that would lead you to believe that the water supplied to London is bad in quality and injurious to health?—I certainly have not. I believe that a great deal of what has been stated upon that point is merely assertion without inquiry. I have been in the habit of being consulted by towns not only in England but on the Continent, and I doubt whether any city in Europe is better supplied than the metropolis either in quantity or quality.

Mr. Quick:—

6009. The quality of the water you say is good?—It is very good indeed for all purposes, not only for domestic purposes but for manufacturing purposes. Brewers and tanners, and those people who use large quantities of water for trade, all prefer the Thames water to any other water that they can get.

The following remarks by Mr. Pole (Appendix O.) also bear on this question:—

Below Lechlade the Thames is canalized, the water being held up by locks, weirs, and sluices at intervals, forming successive ponds.

There appears to be no traffic worth speaking of in a large portion of this navigation; but the weirs have, I have no doubt, a very beneficial influence on the quality of the water, as its flow over them causes great agitation and aëration, and so must promote considerably the breaking up and oxydation of the organic matter. This fact I think ought to receive more consideration than hitherto in the discussion of the general economy of the river.

The towns of Cirencester, Cricklade, Lechlade, Fairford, Northleach, Swindon, Highworth, and some other small places, lie in the basin above this point, but as no systematic drainage by sewers (except to a small extent at Cirencester) is carried out in any of them, I think it may be said that the only contamination of importance received by the water is from the tilled land. And from the absorbent nature of the ground over nearly the whole of the district, this will naturally be much less than in places where the waters flow over retentive soils.

Analyses of the Waters of the Thames and its Tributaries made for the Commission.

186. The analyses, by Drs. Frankland and Odling, of the samples collected by Mr. Pole (see Appendices O, and A X 1 and 2) show the difference in the quality of the water of the Thames, in different parts of its course, and of its principal tributaries, together with the character of the water of some of the main springs feeding these rivers. The facts obtained are important, although we see reason to differ from some of the conclusions which one of the chemists has drawn from them.

Dr. Frankland adds to these analyses the following remarks of his own:—

The conclusions arrived at from the foregoing investigation of the waters of the Thames basin may be thus summarised:—

1. The head waters of the Thames and the waters from chalk wells and springs in the Thames valley contain but a very small proportion of organic matter, which is, however, highly nitrogenized. They are very hard, and, with one exception (the Caterham well water), exhibit a high previous sewage contamination. Although markedly superior to the river waters at present supplied for domestic purposes to the metropolis, they are much inferior to the Welsh and Cumberland samples.

2. All the feeders of the Thames (exclusive of the head waters) which have been examined, are, without exception, ill adapted if not utterly unfit for domestic purposes. They are all decidedly inferior to the Thames itself at Hampton, and consequently none of them could be substituted with advantage for any portion of the present metropolitan supply.

3. The head waters of the Thames are polluted by sewage or manure matters soon after leaving their sources, and on reaching Lechlade are contaminated even to a greater extent than the Thames water delivered in London.

4. The precise effect of the flow of a stream, in purifying the water from sewage or manure matters, cannot be clearly ascertained from the foregoing investigation; but the analytical results demonstrate that at no part of its course does the Thames become freed from the soluble animal organic matters with which it is contaminated, although the total amount of these matters becomes diminished as the stream pursues its course.

5. After leaving its head springs, the water of the Thames is purer and better adapted for domestic purposes at Hampton than at any other point in its course.

6. Irrigation, properly carried out, purifies sewage to a great extent, but not sufficiently to render it admissible into potable water without danger; the risk arising not only from the considerable amount of animal organic matters which the effluent water still retains in solution, but also from the absence of any guarantee for the removal of the germs or other noxious suspended matters which are frequently present in sewage.

Dr. Odling adds as follows:—

It may assist the Commission, in interpreting the results of our analyses, to have their attention drawn to the following points:—

1. That unoxydized nitrogen, or nitrogen in the forms of organic substance and ammonia, is the characteristic constituent of animal excretions; and that if the entire daily excretions of the 800,000 persons living above the Thames at Hampton were added at once to 800,000,000 gallons of water, or the daily quantity of water flowing past Hampton (*i.e.*, if the excretions of one average person were added to 1,000 gallons of water), they would give to the filtered water a proportion of unoxydized nitrogen amounting to ·3 part in 100,000 parts.

2. That whereas, in fresh animal excretions almost the whole of the nitrogen exists in the form of organic substance, and but a minute proportion in the form of ammonia, in ordinary town sewage about four-fifths of the dissolved nitrogen has become changed into ammonia, only one-fifth remaining in the form of organic substance; so that if the sewage of 800,000 persons were included at once in 800,000,000 gallons of water, it would give to the filtered water a proportion of nitrogen in the form of ammonia amounting to ·24 part, and a proportion of nitrogen in the form of organic substance amounting to ·06 part in 100,000 parts.

3. That according to the tables of results, the excess of unoxydized nitrogen in Thames water at Hampton, above that in the Head Springs water, is ·015 part, and the entire amount of unoxydized nitrogen in the water at Hampton, but ·024 part in 100,000, the two waters being alike free from ammonia; whilst, of feeders, &c., of the Thames draining sparsely populated districts, the quantity of unoxydized nitrogen amounts in the Kennet above Hungerford, to ·034 part, including ·003 of ammonia; in the Thames below Lechlade, to ·036 part, including ·003 of ammonia; in the stream from Bagshot sands, to ·046 part, including ·003 of ammonia; in the Wey above Godalming, to ·066 part, including ·001 of ammonia; and in the Thame, to ·075 part, including ·001 of ammonia, in 100,000 parts of water.

187. An examination of these analyses shows:—

	Parts.
1. That the solid residue in 100,000 parts of the *waters of the Thames* and of its *tributaries* in the Oolitic and Chalk area varies from	25·58 to 32·95
And from its *tributaries* flowing through or from the Bagshot and Lower Greensand districts from	7·05 to 18·10
2. That the proportion of *lime* (as carbonate of lime chiefly) in this residue varies in the one case from	11· to 15·03
And in the other from	·68 to 5·73
3. That the *springs* in the Chalk and Oolitic districts contain of solid residue from	28·25 to 32·36
4. That the *lime* in these different springs is in nearly equal quantities, varying only from	14·00 to 14·50
5. That the quantity of sulphuric acid (in combination chiefly as *sulphate of lime*) varies in the tributaries of the Chalk district from	·49 to ·54
Ditto, ditto, Oolitic limestone district from	1·62 to ?
Ditto, ditto, clay and mixed districts from	3·68 to 4·28

Of other inorganic substances the quantities are small.

In the whole course of the Thames, from Lechlade to Hampton, the only resulting difference in the quantity of solid residue is ·56, showing a decrease of from 28·63 to 27·87. Part of the lime present in the springs is precipitated, apparently by exposure to river flow, both in the Thames and the Lee, showing a reduction of from about 14·25 to about 11·50 in the 100,000 parts of water.

188. There are great anomalies in the quantities of nitrites and nitrates present in the springs and in the rivers in different parts of their course. All the springs hitherto examined, whether in the chalk or oolitic districts, contain more of these salts than the river waters do, as estimated by the quantity of nitrogen in combination with them, which varies from ·358 to ·422. From ·358, which is the quantity in the head springs of the Thames, it decreases rapidly to ·157 at Lechlade. It rises again to ·277 below Oxford, decreases to ·245 at Abingdon; is ·205 above and ·211 below Windsor, and falls to ·196 at Hampton. Some effect is no doubt partly due to the addition of sewage matter as the river passes these towns, and we had hoped to obtain a measure of the extent of conversion of organic matter into innocuous nitrates and nitrites by the plan adopted of testing the water before and after it had passed the principal towns on the banks of the river; but the change effected by other causes, especially by the influx of the tributaries, is so much greater, that it becomes difficult, or rather impossible, at present to apportion effects to the relative causes. Thus the high figure below Oxford is in greater part accounted for by that of the Cherwell, which, two miles above Oxford, gave ·264, while again the Thames proper had risen from ·157 at Lechlade to ·218 above Oxford, influenced possibly by the smaller tributaries it had received in its 27 miles flow. At Caversham, above Reading, the quantity had again increased to ·286, whereas just below Reading, after receiving the drainage of this town, it fell to ·148; this arises evidently from the influx of the Kennet, which a little above Reading contains only ·029, while nearer its supply springs above Hungerford this tributary gives ·113. The Thame—the hardest and worst of the tributary waters—contained only the small amount of ·080 of nitrates. Again, the Thames at Hampton is affected on the one hand by the Colne with ·302, and the Wey with only ·090.

It would appear, therefore, that the effect produced by the drainage of towns into the Thames is quite subordinate to the changes produced by the flow of the river, the effects of vegetation, and probably by the action of the mud and silt, which in some of the tributaries, where there is a larger proportion of argillaceous matter present, may have a more efficient action in separating the bases of the nitrates and nitrites. The Thame flows chiefly over argillaceous strata, and the Kennet just before reaching Reading receives the several small streams draining the London clay and Bagshot sands of the district. The Wey has a portion of its drainage from the same formations. The fluctuations in the quantity of nitrates seems to us inexplicable upon the hypothesis of their immediate dependence upon recent organic matter. We should be more disposed, looking at the exceptional quantity present above Reading, in the Colne and at other places where the rivers have been largely fed by springs from the chalk, to refer much of it to supplies furnished by these springs. This, however, requires investigation.

189. The organic matter in solution in the waters of the Thames through its 140 miles course exhibits the same general persistence, accompanied by similar though not parallel fluctuations to those of the inorganic matter and the nitrates. In this case, however, the conditions at starting are very different. The quantity of organic nitrogen, taking that as the test of undecomposed organic matter present in the springs, is at its minimum instead of the maximum shown by the nitrates. The following table shows some of the

results of the analyses made for the Commission by Dr. Frankland which bear on this point:

	Organic Nitrogen.	Organic Carbon.
Amwell Well (taking this water to represent the springs of the Lee)	·009	·076
Otter Spring, the Colne, near Watford	·012	·026
Croydon Well (taking this to represent the spring water of the Wandle)	·007	·040
Syreford and other large springs, forming the main sources of the Thames	·009	·014
By the time the Thames has reached Lechlade these quantities have increased to	·033	·133
And subject to a number of fluctuations they stand on the river reaching Hampton at	·024	·260

190. The effects of town drainage, and the diminution of the quantity of organic matter brought about by the flow of the river, are more apparent in these experiments, but are still far from striking. Thus the quantity of organic nitrogen has decreased from ·033 at Lechlade to ·028 in the Thames above Oxford: after passing Oxford it still stands at ·028, but that is accounted for by the junction of the Cherwell with only ·025 of organic nitrogen; at Abingdon it falls to ·026, rises to ·032 at Caversham, increases to ·049 just below Reading, decreases, 5 miles lower, to ·032, decreases to ·028 above Windsor, rises at Windsor to ·029, and then falls to ·027.

191. In a supplementary report, Dr. Frankland and Dr. Odling call attention to the important fact that "the Thames is chemically purer at Hampton than at any other part "of its course." They account for the reduced quantity of mineral constituents by the influx of the Wey at Weybridge, which, draining a tract of Lower Greensand, Bagshot sands, and London clay, brings down less carbonate of lime, as is rendered clear by the results of their analyses, which show the solid residue in each to be—

Thames at Staines.	Colne.	Wey.	Thames at Hampton.
31·40	32·14	18·10	29·90

of which the lime is in the proportion of—

12·63	13·78	5·73	11·85

The nitrates in the same way give a mean result. They remark, however, that the marked reduction of ·003 part of organic carbon and ·044 part of organic nitrogen in the Thames between Staines and Hampton finds no explanation from this series of analyses, and they attribute it to some exceptional cause, such, possibly, as the precipitation of organic matter, which they show may take place when calcareous waters—such as that of the Colne—are mixed with peaty water like that of the Wey. We would, however, observe that the diminution in the quantity of organic nitrogen in the Thames in the five miles below Reading by ordinary oxidation (for there is no influx of any tributary) is ·017 part, while the ·072 part in the Thame water at Dorchester leaves the Thames water at Caversham, after a flow of about 18 miles, at ·032.

192. The fluctuations in the quantity of nitrogenized organic matter, in summer and winter, which their analyses show to take place, are, however, more remarkable, and need further investigation. They are as follows:

	Filtered Thames Water just below the Weir at Staines.		Filtered Thames Water at Hampton.	
	May 2d.	Oct. 28th.	May 4th.	Oct. 28th.
Organic substances in 100,000 parts of each water:				
Organic nitrogen	·027	·097	·024	·057
„ carbon	·304	·304	·260	·263

Compared to these the slight changes in the quantities of organic nitrogen noted in the Thames water in different parts of its course, from samples taken during the months of April and May, are comparatively insignificant.

193. Although these analyses of the Thames waters will require repetition and extension before the exact value of all the facts can be determined, yet as they relate to the river at one season they may be accepted as relatively correct, and they are sufficient to show at least not only the absence of any increase of objectionable matter in the river from

Lechlade to Hampton, but that the variations in the quality which commence at Lechlade, after showing several temporary changes in many parts of the river's course, fall at Hampton in general to a point as low as at Lechlade, and in one respect, viz., the organic nitrogen, to a point even lower.

It is necessary to remark that the river waters were filtered before analysis, but not the spring waters, which were only left to subside. This must be taken into consideration, as the effect of filtration on organic matter, to which reference is made elsewhere, is of great importance.

194. We cannot conclude this part of our Report without making a few observations on some of the inferences attached to the chemical analyses made for the Commission, as well as on some of the same character accompanying the monthly reports of the Registrar General, as they have been much disputed in the evidence, and as the authority these Reports carry is necessarily great. We refer especially to the interpretation put upon the presence of certain salts as indicating what has been termed "original sewage contamination," and on what are really impurities in water.

It is well known that decomposing organic matter is constantly giving rise to alkaline nitrites and nitrates. Dr. Frankland refers them, not simply to organic matter taken generally, but to sewage or manure matter especially; and the quantity of these salts is made the measure of the estimated "previous sewage contamination" of the different waters, for which a separate column is given. This seems to be an inference which can hardly be accepted. It would be perfectly correct if all the nitrogenized matter supplied to the Thames or other waters was, after conversion into nitrates or nitrites, retained in the water, and if also all these salts could be referred to sewage and manure matter solely. But such is not the case. All the analyses show how variable the quantity of these salts is in different parts of the river's course, and that the quantity present at any place is not so much dependent upon the sewage received as upon the removal which has been effected by vegetation and other causes, by the interference of tributaries, and by the addition from springs; so that, even supposing them to originate solely from animal origin, the residue affords no comparative results as to the amount of original contamination. The interfering causes are too numerous to allow us to assign any value to the remainder. We find it therefore difficult to understand the value of the meaning to be attached to "previous sewage contamination" if by that term it is supposed that we are able to recognize the amount of contamination produced in a river by the addition of the sewage of the towns by which it passes.

If the quantity also of nitrates varied in the inverse ratio of the organic nitrogen some more definite conclusion might be formed; but that is not generally the case. It appears that the sources most free from probable contamination, such as the springs forming the head waters of the Thames, contain in 100,000 parts of water, 3·260 parts of nitrates, whereas the Thames just below Lechlade contains only 1·270, and after experiencing various fluctuations as it flows by Oxford, Reading, and Windsor, still contains at Hampton only 1·640 or only one-half of that in the head springs of the river. The Kennet above Hungerford contains ·830, while just above Reading the quantity is 0. The chalk springs at Amwell give 3·740, while the East London Company's water at London shows 1·077. The water in Croydon well has 5·200, and the Wandle at Mitcham 3·704. The excess in the springs has been referred to manured lands, but this seems offered rather in explanation than as an ascertained fact.

Here the sources most free from possible contamination show the larger skeletons, whilst, after the known large additions of sewage matter made to the Thames at Oxford, Reading, Windsor, Henley, and other places, the proportional quantity of nitrates present in the river at Staines is no greater than at Oxford; so that without an *à priori* knowledge of the facts of the case, the analysis would have failed to indicate them. The Kennet, after flowing through Hungerford and Newbury, would seem by the column of "previous sewage contamination" to be as pure as the waters of Loch Katrine or Bala Lake; the river Lee, to become purer the nearer it comes to London; and the river Wandle, so far from suffering from the addition of the Croydon sewage from the Beddington meadows, would show to more advantage than the water at its source.

Nitrogenous compounds are, in fact, not peculiar to animal substances. They are present in a great number of plants. Their decomposition in either case may give rise to alkaline nitrates, and in the latter lead naturally to their introduction into the surface soil. Nitrites and nitrates are not only the result of the decomposition of sewage and other animal matter, but they are also constantly present in the soil and in springs. M. Boussingault, the distinguished French chemist, in his work on "Chimie Agricole," states that he tested for these salts in soils which were never manured, as in the soil of forests, as well as in soils which were slightly and much manured; that one kilogram

of earth from ground never manured, as for example that of the pine forest on the summit of the Liebfrauenberg hills, contained 0·0041 gramme of nitrates, another pine forest gave 0·0014, and the forest of Fontainbleau 0·0020; whilst a vineyard at Liebfrauenberg gave only 0·007, and a hop ground at Sauer 0·0018, both the latter being highly manured lands. Other cultivated lands gave larger quantities,—some very large. Much depends upon the fall of rain. The same able chemist shows also that nitrates are occasionally found in chalk, in some marls, faluns, and in gypsum, while springs equally free from known sources of contamination give very variable results. In lakes he generally found the quantity small. In some wells, on the other hand, he found as much as from half to one gramme per litre.

We cannot help therefore concluding that considerable sewage contamination may take place without indication of its presence by nitrites and nitrates, whilst in other cases these salts may be derived from vegetable matter and from springs which cannot be suspected of having been contaminated with true sewage matter. Their presence in moderate quantity does not indicate with certainty the presence of old sewage matter, nor does their absence prove freedom from such matter. At the same time, where an excess of these salts occurs, as in some wells, they should be regarded with suspicion, and form cause for immediate inquiry; for that they are generated largely by town sewage is indisputable.

Nor can we agree with some eminent authorities in looking at river water in a solely chemical point of view, and speaking of the presence of the 10 to 20 grains of mineral matter in the gallon as *impurities*. So, chemically speaking, they are, but as this seems to be almost a normal condition of river waters, we should not be disposed to consider this term an appropriate one to be applied to substances so constantly present in natural springs and streams.

And further, we cannot but consider it unphilosophical when, in addition to treating as "impurities" substances perfectly harmless even in much larger quantities, the minute quantities present in a gallon, or any other small measure of water, are multiplied by taking masses of water, such as the individual never has to deal with, and given to the public in figures so large as to tend to cause misconception, and perhaps unnecessary alarm in the minds of those not conversant with all the conditions of the case. It would be as just to speak of the small proportion of carbonic acid present in the atmosphere, equally in populous cities and in the Alps, as an impurity, and to startle those unacquainted with the subject by giving in some large figures the total quantity of that gas present in the atmosphere of London.

The question of main and vital importance is not the presence of a moderate quantity of mineral matter, which is of secondary importance, but refers to the presence of organic matter of an objectionable quality. Few waters are free from organic matter, but all organic matter is not objectionable in small quantities.

It is contended, and no doubt with truth, knowing beforehand the probabilities of the case, that although the soft waters of the mountainous districts of England and Wales contain as much organic matter as the Thames water, there is an essential difference in its quality. Still the evidence is by no means conclusive even on this point. Whilst on the one hand there is clearly far less objectionable matter introduced into the former, on the other hand the remarkable power of oxydation possessed by running water, admitted more or less by all chemists, so destroys and removes organic matter that the water regains in a great measure its original purity, either unassisted or else further aided by filtration. It is possible also that the deposition of carbonate of lime, which is known to take place in rivers where the saturation has been in excess of a given quantity, may carry down with it, as it does in Clark's process, a certain quantity of organic matter. The singular fact also noticed by Dr. Frankland and Dr. Odling, of the precipitation of nitrogenous organic matter by the influx of a more peaty water into the Thames is of great interest.

Where a minute quantity only of organic matter escapes destruction, it would seem that chemistry is not yet sufficiently advanced to pronounce authoritatively as to its exact quality and value, and with microscopic living organisms, especially, chemistry is incompetent to deal, and other modes of examination are needed.

Where the organic matter is present in quantities sufficient to diminish the free oxygen in the water, or to tend to putrefactive decomposition, danger is to be apprehended, and considering the nature and scale of the experiment now about to be made with respect to the disposal of the sewage of towns, too much care and watchfulness cannot be exercised in face of the risk which any neglect or oversight might give rise to.

Whatever may be our difference of opinion with respect to some of the conclusions, we

cannot place too high a value on the independent analyses of the water supplied to London, published monthly in the comprehensive and important Reports of the Registrar General.

B.—ON THE FUTURE INFLUENCES LIKELY TO AFFECT THE QUALITY OF THE WATER FROM THE BASIN OF THE THAMES.

195. We must look forward to the prospect of a probable increase of the quantity of sewage coming from the towns, and which if allowed to be poured into the river and its tributaries, would no doubt have a serious effect on the quality of the London supply.

The Chemical Commission of 1851 say:—

"The contamination by sewerage, however, cannot fail to become considerable and offensive with the increase of population, and the more efficient and general drainage of towns. And it appears to be only a question of time, when the sense of this violation of the river purity will decide the public mind to the entire abandonment of the Thames as a source of supply, unless indeed artificial means of purification be devised in the meantime and applied."

And again:—

"The removal of the nuisance complained of, however, can never be complete, but only partial. The contamination from navigation and the river population must be increasing rather than otherwise; while gas-works and other indispensable chemical manufactories, which at present pour their refuse products directly into the river, would necessarily continue to do so, as these products are often of a kind not admissible into ordinary sewers."

196. This question, however, has been grappled with by the Rivers Pollution Commission, who in their report on the Thames, March 1866, have treated at considerable length the subject of the purification of the river, not only from house and town sewage, but also from the refuse of manufactories and other pollutions.

In regard to the former they came to a conclusion expressed as follows:—

"That from experiments conducted under the Sewage Commission, and evidence taken on the subject of sewage utilization, and also from our own inspections and investigations, and from the evidence appended to this report, we believe that town and house sewage may be so utilized on land as to preserve the river from the danger of pollution."

They proposed certain changes in the governing body in whom was vested the conservancy of the river, and added the following recommendations:—

"That, after the lapse of a period to be allowed for the alteration of existing arrangements, it be made unlawful for any sewage, unless the same has been passed over land so as to become purified, or for any injurious refuse from paper-mills, tanneries, and other works, to be cast into the Thames between Cricklade and the commencement of the metropolitan sewerage system, and that any person offending in this respect be made liable to penalties to be recovered summarily.

"That it be made incumbent upon the conservators to see to the enforcement of the above prohibitions against pollution of the river, and that for this purpose power be given to them to visit and inspect works, and, after due notice, to close the outlets of sewers, drains, and discharge-pipes into the river within the limits described in the last preceding recommendation.

"That, subject to proper safeguards to prevent abuse, powers be given to local authorities to take land compulsorily for the purpose of sewage irrigation, to an extent not exceeding one acre for every 50 persons whose sewage is to be applied.

"That the conservators be empowered to levy upon all waterworks, taking water for domestic or trade purposes from the River Thames, a rental in proportion to the volume abstracted; the maximum of such rental to be named by Parliament."

197. In consequence of these recommendations an Act was passed in August of the same year (29 & 30 Vict. cap. 89), intituled "An Act for vesting in the Conservators of "the River Thames the Conservancy of the Thames and Isis from Staines, in the county "of Middlesex, to Cricklade, in the county of Wilts, and for other purposes connected "therewith." It altered the constitution of the existing Conservancy Board of the Thames, and considerably enlarged their powers and the extent of their jurisdiction.

The following clauses relate to the improvements affecting the quality of the water of the river:—

"52. The Conservators shall cause the surface of the Thames to be (as far as is reasonably practicable) effectually scavenged, in order to the removal therefrom of substances liable to putrefaction.

"63. From and after the passing of this Act it shall not be lawful for any person to do any of the following things, namely,—

"(1.) To open into the Thames any sewer, drain, pipe, or channel with intent or in order thereby to provide for the flow or passage of sewage, or of any other offensive or injurious matter:

"(2.) To cause or, without lawful excuse, (the proof whereof shall lie on the person accused,) to suffer any sewage or any matter aforesaid to flow or pass into the Thames down or through any sewer, drain, pipe, or channel not at the passing of this Act used for that purpose:

"(3.) To open into any river, stream, cut, dock, canal, or watercourse communicating with the Thames at any point within three miles of the Thames, measured in a direct line therefrom, any sewer, drain, pipe, or channel with intent or in order thereby to provide for the flow or passage of sewage or of any matter aforesaid in such manner that the same will be carried or be likely to be carried by, through, or out of that river, stream, cut, dock, canal, or watercourse into the Thames:

'(4.) To cause or, without lawful excuse, (the proof whereof shall lie on the person accused,) to suffer any sewage or any matter aforesaid to flow or pass into any such river, stream, cut, dock, canal, or watercourse at any point within the distance aforesaid down or through any sewer, drain, pipe, or channel not at the passing of this Act used for that purpose, in such manner that the same will be carried or be likely to be carried by, through, or out of that river, stream, cut, dock, canal, or watercourse into the Thames:

"If any person does any act or thing in contravention of this enactment he shall for every such offence be liable on summary conviction to a penalty not exceeding one hundred pounds, and to a further penalty not exceeding fifty pounds for every day during which the offence is continued after the day on which the first penalty is incurred.

"64. Whenever any sewage or any other offensive or injurious matter is caused or suffered to flow or pass into the Thames, or is caused or suffered to flow or pass into any river, stream, cut, dock, canal, or watercourse communicating with the Thames, at any point within three miles of the Thames, measured in a direct line therefrom, in such manner that the same is carried or is likely to be carried into the Thames, then and in every such case, whether any such sewage or other matter aforesaid had or had not been so caused or suffered to flow or pass before the passing of this Act, the Conservators within a reasonable time after knowledge of the fact shall and they are hereby required to give notice in writing under their common seal to the person or body causing or suffering the same so to flow or pass, to the effect that they require him or them to discontinue the flow or passage thereof as aforesaid within a time to be specified in the notice, not being in any case less than twelve months or more than three years; provided that the Conservators may, if they think fit, at any time and from time to time extend the time specified in the notice by another notice in writing under their common seal; but nothing in this section shall authorize the Conservators, until the expiration of six months after the passing of this Act, to give to the owner or occupier of any mill or work a notice requiring him to discontinue the flow or passage as aforesaid of any liquid matter produced or used in the manufacture of paper or in any process incidental thereto."

"65. Subject to the provisions of this Act, any person to whom any such notice is given by the Conservators shall, notwithstanding anything in any other Act, within the time allowed by the notice, discontinue the flow or passage of the sewage or other offensive or injurious matter to which the notice refers, and if any person fails to do so he shall be guilty of a misdemeanor, and shall be liable, on summary conviction thereof before two or more justices, or on conviction thereof on indictment, to a penalty not exceeding one hundred pounds, and to a further penalty not exceeding fifty pounds for every day during which the offence is continued after the day on which the first penalty is incurred."

In consideration of the improved quality of the water which it was assumed would result from these measures, the five metropolitan water companies drawing water from the river agreed and were bound by clauses 59 to 61 of the Act to pay to the Conservancy Board, each the sum of 1,000*l.* per annum, in addition to certain sums previously agreed to be paid by some of them.

198. We have had before us the chairman, Mr. Thorpe, the secretary, Captain Burstal, and the engineer, Mr. Leach, of the Conservancy Board, and we learn from them that they have served the notices required by the Act, on all the local authorities, from Oxford downwards, to discontinue discharging their sewage into the river.

We are not aware what the result of these notices has been; probably sufficient time has not elapsed to carry out the works necessary, but we presume we may take it for granted that the provisions of the Act will be duly enforced, and that if any difficulties should arise in doing so the subject will receive the attention of the Legislature.

199. Presuming, therefore, the sewage to be used upon the land, it only remains to inquire what amount of benefit may be expected from this measure. It must be borne in mind that the use of liquid sewage for irrigation does not entirely intercept it; for after deducting a certain loss by evaporation and absorption during the irrigation process, the remainder must still flow off into the streams; and hence the question becomes, to what extent will this latter portion be improved in quality over its original state of simple sewage?

200. This question presented itself to the Conservancy Board, and they referred it to three eminent chemists, Drs. Letheby, Frankland, and Odling, desiring them to report— 6851 et seq.

"Whether fluid which has been mixed with sewage can be so purified as to be admissible into the river Thames, and if so, in what manner it may be done; and to fix a standard of purity."

The report given in answer to this question is printed in Captain Burstal's second evidence. The referees examined carefully the application of the sewage irrigation systems

in use at Croydon, Rugby, Carlisle, Worthing, Leicester, and Hertford, and give their opinion that if the process is performed under certain conditions, the defæcated fluid is remarkably improved in quality and may be safely discharged into any running stream. Dr. Frankland, however, adds an opinion as follows:—

"P.S.—The conditions under which fluid which has been contaminated with sewage may be admitted into the Thames, as prescribed in the foregoing report, will, I have every reason to believe, preserve the river from being offensive to the inhabitants upon its banks; but, whilst thus far agreeing with my colleagues, I wish it to be distinctly understood that, in my opinion, such fluid can only be safely admissible into the Thames on condition that the water is not afterwards used for domestic purposes. Neither by the processes of purification mentioned above, nor by any others of a practical nature, at present known, can water which has once been contaminated with sewage be, in my opinion, again rendered safe for human use."

The Board referred Dr. Frankland's opinion to the two other chemists, who expressed their dissent from it.

Dr. Letheby says:—

"In reply to your letter of the 5th instant, I have to state that I cannot at all agree with Dr. Frankland that the water of the Thames, after receiving defæcated sewage water, is unfit for domestic use; for after a large practical acquaintance with the subject as it is observed in the principal streams and rivers of England, I have arrived at a very decided conclusion that sewage when it is mixed with about 20 times its volume of running water and has flowed a distance of 10 or 12 miles, is absolutely destroyed; the agents of destruction being infusorial animals, aquatic plants and fish, and chemical oxydation.

"I have stated this in evidence before Parliamentary Committees and Royal Commissions, and I am satisfied that the opinion is well founded."

Dr. Odling says:—

"From many considerations, and especially from the fact that the undefæcated sewage, &c., discharged into the Thames above the source of the present water supply is not recognizable in the water at present supplied, I am decidedly of opinion that the water of the Thames will not be rendered unfit for human use by receiving sewage matter defæcated in the manner described, unless the proportion of such defæcated sewage should become much larger than there is any reason to anticipate."

201. Many able witnesses have given us evidence on this subject.

Mr. Simon says:—

2817. But assuming that the powers given to the Commissioners of the River Thames Conservancy are fully carried out, which amount to an absolute prohibition as to the towns drawing their sewage directly into the Thames, would not that, in your opinion, be an immense advantage in purifying the present supply of London, which is taken now above Teddington lock?—Yes, it would be a very great gain.

2818. Supposing that the prohibition were extended to all sewage going directly into the river at any part of it, and that under the powers which are given to the Thames Conservancy Board, they compelled the towns to distribute their sewage for the purposes of irrigating the land, and consequently that all the water falling on the surface merely came into the river after having passed through the soil, do you think that in that case the Thames water taken above Teddington lock would still be polluted, or should you consider it to be practically free from pollution?—Assuming a sufficient thickness of soil, I should so consider it.

2819. Can you form any opinion at all in that case as to whether the water taken above Teddington lock would still be impure and unwholesome, supposing, for instance, it had travelled exposed to the atmosphere for 15 or 20 miles of river?—I should think it quite a safe water as regards the danger that we are speaking of.

2839. Supposing that those upper towns are driven to deodorize their sewage, or to apply it for irrigation to the land, would the water that must pass off ultimately into the river be sufficiently purified, do you think, so as not to affect the river prejudicially?—A speculative answer is not worth much upon this subject, and I can only give a speculative answer at present. I think it very likely that the water would be harmless, but possibly the result might show that the water could not be deemed quite safe.

Dr. Parkes says:—

3230. Assuming that under the powers of the Act of last session all that sewage will be diverted in the first instance from the Thames and used upon land, would you not consider that the result would be that it would be very much purified beyond what it is at the present moment?—I have no doubt of that at all, but it is impossible to say what the amount of purification would be, because I do not know what the conditions would be of the irrigation of land in proximity to the river, or the amount of water which would pass through the land.

3231. All that would be laid upon the chalk and oolites would be almost entirely absorbed by the land, would it not?—Yes.

3232. But where the sewage is laid upon the clay it would come off more rapidly?—Yes.

3233. Do you think that if that plan were carried out there would be still an impurity in that water sufficient for you to say that it ought not to be used?—I should feel very great difficulty in answering that question.

3234. You seem to say now that from Dr. Frankland's analysis it is what you would call a suspicious water?—I should say so, because there has been certainly organic matter in it derived from sewage, and though that has been oxydized to a considerable extent, still, as showing previous impregnation, and as indicating that there might be a further passage of sewage into the water, and the possibility of a less degree of oxydation at certain times, I should call it a suspicious water.

3235. Then until that purification has taken place which is now in progress, and the water is analysed afterwards, you think that no opinion could be formed upon that point?—I should like to know whether it would be effectual or not in completely diverting the sewage from the Thames, and I should hardly think it possible to form any opinion upon that point.

Dr. Letheby says:—

3891. "I think that none of the sewage discharged into the Thames can at the present moment be discovered at Hampton, but nevertheless it is very possible that there may be a still further improvement of the Thames water

by the adoption of these measures. Certainly there will be an improvement in this manner, that if the discharge of the sewage into the Thames were to go on increasing during the next 20 or 30 years, as it has been during the last 20 or 30, we should then probably have such an excess of sewage in the water of the Thames as would render it very unwholesome."

Dr. Frankland gives evidence as follows:—

6376. Supposing the sewage were diverted from the Thames in pursuance of the existing law as carried out by the Thames Conservancy Board, would your objections be removed with regard to the Thames water being suitable for the supply of London?—They would be removed so far as the actual sewage was concerned. I should still object, although in a mitigated degree, to the drainage from cultivated land flowing into the Thames. But in speaking of the diversion of the sewage from such towns as Oxford and Windsor, the mere diversion of that sewage so as to throw it upon land, and then allow it to drain or to make its way into the Thames, would not overcome my objection to the water on the ground of the sewage, because I do not think that sewage which has been merely passed over land, or even through land, can be safely allowed to mix with water that is to be employed for domestic use.

6377. Then your gathering ground for the supply of large towns must necessarily be very limited if that view prevailed, that it should pass over no cultivated land, and that the smallest particle of sewage makes it unsuitable for domestic purposes?—If you have no choice of water, of course it would be much preferable to drink water that was contaminated only from the drainage from manured land, as compared with that which was contaminated directly by sewage. But sewage that has been allowed to flow over land, and which perhaps does not sink into the land at all, would, I should think, be much more objectionable than the water drainage from cultivated land, and which is manured principally from animal as distinguished from human manure.

6378. In the case of the 250 acres of land at Croydon upon which the sewage of that town is spread, the water running off into the Wandle is to the eye perfectly pure; have you ever examined any of that water to ascertain whether there is still held in solution that which is prejudicial to human health?—I have examined that particular water which you have mentioned, and also a number of other similar waters running off land upon which sewage has been placed. Those examinations have been recently made by Dr. Odling and Dr. Letheby and myself for the Board of Conservators of the Thames, and I may say that the substantial result, at least what I myself would say was the substantial result, of those examinations is, that about four-fifths of the sewage matter is destroyed under favourable circumstances, but that is all you can calculate upon. So that if you were to have all the sewage which is at present poured in an unmitigated form into the Thames distributed over the land as it is done at Croydon, you would reduce the amount of contamination of the Thames to one-fifth of what it is at present. In other words, if the population increased to five times its present amount, in the Thames basin the contamination would be as great as it is at the present day, after the sewage had passed over the land.

6396. Assuming that the Act of Parliament which was passed last session for preventing the pollution of the river Thames is efficiently carried out, and that no sewage is directly discharged into the river, and assuming also that those companies adopt proper modes of filtration, would not this specially objectionable case be to a great extent met?—With regard to the muddiness of the water, it would completely, but not with regard to the wholesomeness completely. The unwholesomeness of the water would doubtless be mitigated by otherwise disposing of the sewage, or rather, I should say, by passing the sewage over the land before its admission into the Thames; but I do not think that even after that such a proportion of sewage would be innocuous when admitted into the Thames.

Dr. Odling says:—

6443. But are you of opinion that, supposing the Act of last year were faithfully carried out, and the sewage were intercepted from the river Thames, the water on the whole would be a suitable water for the supply of London for domestic purposes?—Yes, I am.

Sir Benjamin Brodie says:—

6992. Are you prepared to express an opinion on the result of the application of sewage to the land, the water being afterwards discharged into a river, whether it would or would not be injurious to health after its filtration through the soil?—No; I think here again the same obscurity prevails, only to a less extent. I think it is certain that the sewage water must be benefited very materially indeed by being filtered through the land, and I have that opinion because I know that in the porous material of the land the processes of oxydization which destroy the injurious sewage matter go on much more rapidly and efficiently than they do otherwise, and not only that, but that the land operates as a filter and stops, mechanically, a large portion of the solid injurious matter of the sewage; but if you ask me whether the water that runs out from the land, although it may be bright and clear, is a good beverage, I do not know how we are to answer that question except by giving the water to human beings to drink, and by long observation of its effects.

6993. Then, although the process of filtration may catch and retain all that is held in mechanical suspension, still in your judgment there may be elements passing off in solution that might be injurious to health?—I think there may be, certainly, and not only in solution, but even not in solution; I mean by that that there may be even solid matters, organic germs, which would be so small that they would pass through the filtering material employed.

6994. And which might be unobservable to the eye?—Unobservable altogether to the senses, and yet which might be extremely detrimental to the health; but here again you cannot say that they are detrimental to the health, you can only say that they may be so.

7039. What course do you consider the most efficacious one to get rid of sewage contamination from the towns on the river?—The best is not to put the sewage with the river at all, that is the best answer I can give, and, indeed, that is really the only course by which you can be certain that you have not got it in. I certainly do think it a very good thing to employ the processes used for the filtration and destruction of sewage, and they are *pro tanto* beneficial. They really help the matter a good deal, but I do not think that they are entirely effectual. There is no known process that I am aware of for, on a large, scale destroying the injurious qualities of sewage.

7040. By throwing it upon the land you absolutely get rid of a large portion of the sewage, and what is left is somewhat improved?—Very greatly improved, but I should not like to take a glass of water and drink it from just the spot where it went into the river, still less to make it one's daily and habitual beverage.

Dr. Angus Smith says:—

7204. Is it your opinion that after the application of sewage to the land the water filtered off and running into the river would be harmless?—If the land or the filter is not overburdened with sewage, that is to say, if no more is allowed to pass through than can be properly oxydized, then complete purification must take place.

7206. Then, as a rule, are you of opinion that it would be safe to apply sewage to land and allow the water to run off into a river which is the main source of supply to a town for domestic purposes?—It is certainly safe to apply some. I am not able at this moment to say how much. I am not able to say, considering the new plans of irrigation proposed, that it would be proper to load the neighbourhood of a large town with sewage, and collect the water from it and use it for the town. I am inclined to think that it would not be safe; but in a thinly populated agricultural country I think we have no reason to believe that any danger can occur. . . . . I therefore conclude that it is a question of quantity, how much sewage can be put upon the land.

Mr. Hawksley says:—

5074. Are you aware that the Thames Conservancy Board are now clothed with power to call upon all the local authorities on the banks of the river, up to and including Oxford, to divert their sewage and other polluting matter from finding its way into the river?—Yes.

5075. Of course the river would be greatly improved if that principle were adopted uniformly up the river?—The river would be very much improved near the towns themselves, but at considerable distances from the towns it would have no effect whatever, because all those matters are exceedingly decomposable in the presence of oxygen and become decomposed entirely by oxydization. There is no such thing as a particle of fæcal matter put into the Thames at Oxford finding its way down to Hampton Court. It is all burnt up in fact by the combustion set up by the oxygen.

Mr. Greaves says:—

5169. Have you seen the report which has just been issued out from the River Pollution Commissioners?—Yes, I have.

5170. They recommend that the same course should be followed in the Lee as had been adopted by Act of Parliament with regard to the Thames, but giving power to a new body to prevent the pollution of the Lee for the future. If that were carried out do you think it would add to the good quality of your water?—I have not the least doubt that it would.

202. During the inquiry our attention had been called to the improvement made in the water of the river Wandle by the sewage irrigation practised at Croydon, and as this example of the process was so accessible, we requested Mr. Pole, when collecting the samples of water from various parts of the Thames basin, to visit these works and to take specimens of the sewage before and after defæcation, and to submit them to Drs. Frankland and Odling for analysis. Mr. Pole's report will be found in Appendix O; he gives a general description of the process, and adds—

When I saw the system at work on the 11th May, although the sewage was foul and dirty when it went on to the land, the water running off was quite bright and clear, without any appearance of foul deposit in the channel. I noticed several fine trout in the river, near the point of discharge, as well as in other places farther down.

It is worthy of remark that the plan here adopted, of allowing the sewage to travel slowly over the land, in constant agitation among the blades and stalks of the vegetation, appears to me peculiarly favourable for the oxydation of the impurities by the action of the atmosphere, which I have no doubt powerfully aids the purifying action by vegetable absorption.

The report of the chemists will be found in Appendices A. X. (1 and 2); it shows that in the diluted condition in which the Croydon sewage is applied to the land, it contains only 11·6 grains more of solid matter (or 43·6 parts in 100,000 parts evaporated to dryness) than the well water of Croydon. In this undecomposed sewage water the ammonia has increased from ·001 to 2·191, and the organic nitrogen from ·007 to 1·156, whilst the nitrogen, as nitrites and nitrates, stands at ·000, whereas the Croydon well water contains ·551. After flowing off the land, the sewage contains only 34·4 parts per 100,000 of total solid residue, the ammonia being reduced to ·002, and the organic nitrogen to ·037, and the nitrogen, as nitrites and nitrates, has increased to ·317. At Mitcham, one mile lower down, the water of the Wandle contains only 31·0 parts of solid residue, or one part less than the Croydon well water, the ammonia has disappeared, the organic nitrogen has decreased to the extent of ·007, and the nitrogen, as nitrites and nitrates, has further increased to ·403. Dr. Frankland considers this amount of purification exceptional, as the quantity of solid impurity in the sewage water, as it flows off the land into the Wandle, would appear to vary according to the rainfall and the season of the year.

According to chemical analysis, the Wandle at Mitcham will contrast fairly with other river waters. The amount of contamination effected by the Croydon sewage, which, however, is weaker than London sewage, almost disappears after the river flow of three furlongs, and a mile lower down all excess of solid impurity has disappeared, the organic nitrogen only being in excess of the quantity existing in the Croydon well water. On the other hand it has to be observed that, notwithstanding the large and constant introduction of town sewage at Beddington, the nitrates and nitrites in the Wandle

at Mitcham are present in less quantities than in the Croydon well water, or than in many of the oolitic and chalk spring waters of the Thames basin. The following table gives some of the comparative results obtained by some of the analyses made for the Commission. It shows the condition of the Wandle 1½ mile below the place where it receives the Croydon sewage, as contrasted with the waters of the Thames and the Lee in places free from town sewage. The quantities are given for 100,000 parts of water.

	River Wandle at Mitcham.	Lee above Hertford.	Thames above Reading.
Total solid residuum	31·0	25·88	32·7
Ammonia	·000	·000	·001
Nitrogen as nitrates	·403	·246	·286
Organic nitrogen	·024	·025	·032
„ carbon	·099	·125	·291
Hardness before boiling	21·1	19·9	21·
Do. do. by Clark's test	14·8	13·9	14·7
Hardness after boiling	9·7	2·1	8·2
Do. do. by Clark's test	6·8	1·5	5·7

WATER FROM THE LEE VALLEY.

203. Our remarks hitherto have been directed principally to the quality of the water from the main stream of the Thames, but they apply also very generally to that from the River Lee.

204. The Rivers Pollution Commission, in their report on the Lee, dated May 1867, point out that the river, above the lowest intake of the water companies, is polluted by the sewage of Luton, Hertford, Ware, Bishop-Stortford, and many other places, as well as by manufacturing refuse of several kinds. In some towns attempts have been made to purify the sewage by different processes before its discharge into the river.

The New River are in the best position as to quality, as they escape the sewage of Hertford, Ware, and all below, and have moreover in their supply a large proportion of pure water received directly from the chalk.

The East London Company's intake is considerably lower, but still their supply is considered wholesome by the Rivers Commission, who report on it as follows:—

"With regard to the quality of the water, the water drawn at Ponder's End is not of course so pure as that taken by the New River Company higher up the stream, because the river in its course over the intervening space has received additional impurities from towns and places, as already detailed under the head of pollution, but this difference is greatly diminished by the fact that between Hertford and Ponder's End the Lee has been reinforced by a large accession of fresh water from the land springs which break out from the chalk into the bed of the river. The result is, as the analyses show, that the East London Waterworks Company are able to obtain a fair wholesome water. The company have gone to great expense to improve the water before it passes to their filter beds, by the construction (under statutory powers) of Catchwater Dyke to intercept sewage of certain towns above the intake, and to deliver it at a point below. In a bill now before Parliament the East London Waterworks Company proposed an extension of this system of intercepting sewers."

The Commission, however, came to the conclusion "that it is expedient that more "stringent measures be adopted to protect from pollution that portion of the metropolitan "water supply which is derived from the river Lee," and they made recommendations with that object.

205. In 1867 the Board of Trade directed an inquiry to be made, through Captain Tyler, into the severe outbreak of cholera which had taken place in 1866 in the east of London, and which had been ascribed principally, if not solely, to the bad quality of water supplied by the East London Waterworks Company. This case has been frequently mentioned in evidence before us, and it appears that by some faulty arrangements at the East London Works the foul waters of the lower part of the river Lee were admitted into the company's reservoirs.

The conclusions arrived at by Captain Tyler are expressed in the following extract from his Report:—

"The disease was, undoubtedly, very fatal during the visitation of last autumn in the metropolis, in the East London Company's field of water supply, and especially in the districts which drew principally from the Old Ford reservoir. There were, on the other hand, other localities, chiefly on high ground and of a better class, such as Stamford Hill, Leytonstone, Wanstead, Woodford, Buckhurst Hill, and Walthamstow, parts of which

are supplied exclusively from that reservoir, which were nearly or quite free from it. Silvertown and North Woolwich were exceptions, the former in the early part, the latter throughout the epidemic. All the houses in these latter places are on constant supply from the North London Company; and the disease was very fatal in certain localities near the East London Company's field of supply, where no water that they supplied could have been an exciting cause. The want of better drainage had, no doubt, much to do with the intensity and duration of the epidemic; but the mortality declined from the 1st and still more from the 9th of August; while the Metropolitan Board of Works commenced their pumping operations to divert sewage from the River Lee and the Limehouse Cut into the northern outfall sewer only on the 24th of August. The Lee must have been contaminated at Old Ford at an early period of the epidemic. The covered reservoirs at Old Ford may have received from the river at different times, as they were partially emptied, some of the poison; and the water supply of some of the districts drawn from those reservoirs may thus at different times have been to some extent infected. Considering this possibility of infection, and looking to the effects which were only too apparent in the general field of supply from Old Ford, a case of grave suspicion exists against the water supplied by the East London Company from Old Ford, and that proximity to absolute proof at which I hinted in commencing this subject has thus been nearly reached. But any poison so distributed would have been in a condition, if it were soluble in water, of considerable dilution, and I am not prepared on that account, as well as in consideration of the deplorable state in other respects of their district, to go so far as the memorialists in asserting that this water was 'the principal if not the sole cause of the fearful mortality from cholera.' I believe, however, that if, as is possible, choleraic poison did find its way into the company's mains, it must have passed directly from the River Lee into the closed reservoirs and I have no reason to believe that it was distributed in the water which was so improperly supplied to the district from the open reservoir."

But whatever may have been the connexion of the East London water with this outbreak of disease, it is clear that the evil arose from an accidental circumstance, and therefore affords no argument against the quality of the Lee water when taken under proper conditions, at the upper part of the river.

206. The House of Commons Committee of 1867, who devoted considerable attention to the Lee, state:—

"Your Committee having received scientific evidence of the present quality of the water supplied by the New River Company and the East London Company, are satisfied that, as far as chemical or other science affords the means of judging, the water is not only wholesome, but compares favourably with that supplied to other places."

The Committee noticed the pollution of the river, and after making some suggestions in addition to the conclusions of the Rivers Pollution Commission, they recommended that a bill should be introduced into Parliament to provide remedial measures.

207. This was done, and on the 31st July 1868 there was passed "An Act to make better "provision for the preservation and improvement of the River Lee and its tributaries, "and for other purposes" (31 & 32 Vict. cap. 154).

The provisions of this Act for excluding sewage and other contamination from the river are generally of the same nature as those enacted for the Thames; making, however, a special exception of the town of Luton, which is allowed to use a chemical purifying process instead of applying the sewage to the land.

WATER OF THE KENT COMPANY.

208. The water of this company is about four or five degrees harder than that of the Thames or the Lee, but in other respects it is fully equal to them, if not superior, on account of its smaller quantity of organic matter. Objection has been taken to the large quantity of nitrates and nitrites in this water, but we have already pointed out that this is not an unusual feature in the water of springs far removed from sources of pollution, as in those of the oolite at the head of the Thames valley, and the chalk.

FILTRATION.

209. It is absolutely essential to the good quality of the Thames water that it be effectually filtered. The Chemical Commission remarked in 1851 that the effect of ordinary filtration through sand was very decided on Thames water, as it appeared to be upon chalk waters in general. The river water, they remarked, could thus be easily obtained, under usual circumstances, entirely free from suspended solid matter or mechanical impurities. More modern experience seems to lead to the belief that filtration also acts, though probably in a way less understood, in improving the quality generally. The analyses in Appendix AG, by Messrs. Letheby, Odling, and Abel, which give the comparative qualities of filtered and unfiltered water, clearly show the advantage gained, as will be seen by the following extract:—

General Results.	Thames Companies.		New River.		East London.	
	Unfiltered.	Filtered.	Unfiltered.	Filtered.	Unfiltered.	Filtered.
	Grains.	Grains.	Grains.	Grains.	Grains.	Grains.
Dissolved matter, per gallon	20·825	19·479	22·402	21·550	24·940	24·360
Of which organic and other volatile matter	1·261	0·976	0·702	0·567	0·915	0·300
Suspended matter, per gallon	0·830	0·034	0·241	0·095	0·561	0·047
Of which organic and other volatile matter	0·173	0·005	0·033	0·014	0·045	0·023
Hardness before boiling (degrees)	14·4	13·3	15·5	13·5	14·4	14·0
„ after „ „	5·3	4·6	4·2	4·0	5·0	5·0
Dissolved gases, per gallon (cubic inches)	13·77	13·85	13·95	12·75	12·51	13·75
Dissolved oxygen, „ (grains)	0·796	0·825	0·906	0·906	0·891	0·752
Oxygen required to oxydise organic and other matter (grains)	0·146	0·134	0·115	0·069	0·090	0·095
Ammonia, per gallon (grains)	0·003	0·002	0·001	0·001	0·004	0·003

Mr. Wanklyn's letter, Appendix AK, says,—

"The water of the Thames at Hampton Court, where the companies draw their supply of water, is not very good, as it exists in the river; but after the filtration effected by *some* (but not all) of the companies, it becomes excellent, and in point of purity from organic nitrogenous matter is then fully equal to the water supplied to Manchester, Edinburgh, or Glasgow."

All chemists agree on the importance of filtration.

210. Filtration was made compulsory by the fourth clause of the Metropolis Water Act, which runs as follows:—

"IV. From and after the 31st day of December 1855, every company shall effectually filter all water supplied by them within the metropolis for domestic use before the same shall pass into the pipes for distribution, excepting any water which may be pumped from wells into a covered reservoir or aqueduct without exposure to the atmosphere, and which shall not be afterwards mixed with unfiltered water."

211. All the companies profess to comply with this provision, but the evidence shows that the filtration has been imperfectly carried out. In the Registrar General's annual summary for 1867 occurs this passage:—

"It is much to be regretted that the London waters are not more effectively filtered before distribution. Only on one occasion during the whole year have I obtained a transparent sample of water from the Southwark Company's main. The Grand Junction and Kent Company's waters were turbid four times out of 12, the Chelsea thrice, and the West Middlesex, Lambeth, and East London twice out of the 12 occasions when the samples were drawn for analysis."

In every succeeding monthly report the same complaint has arisen.

212. We call special attention to this neglect to comply with the provisions of the Act. The process of filtration presents no difficulties, all that is wanted being a sufficient area of filtering surface. There seems to be no efficient means of enforcing an observance of this provision of the Act, and the neglect of the companies to comply with it, notwithstanding the repeated attention drawn to the imperfect filtration, shows the necessity for some change in the system of supervision to which the supply of the metropolis is subjected.

GENERAL REMARKS BY THE COMMISSION ON THE QUALITY OF THE WATER FROM THE THAMES BASIN.

213. The evidence before us leads us to the conclusion that the Thames water has many good qualities which render it peculiarly suitable for the supply of the metropolis, and which give it, in some respects, a superiority over the soft waters usually obtained from high gathering grounds. When properly filtered it is clear, bright, colourless, agreeable, and palatable, and the amount and nature of its saline constituents are considered by many to contribute to its general acceptability for drinking. It is well aërated, has good keeping qualities, and is unusually safe as regards action on lead and iron.

On the Organic Impurities.

214. The evidence we have collected on this subject presents great diversities of opinion; but there is one result which, we think, is clearly deducible from the facts before us, namely, that in the present state of chemical science, analysis fails to discover,

in properly filtered Thames water, anything positively deleterious to health. Whatever may be the difference of opinion with respect to the time required for removal of all the objectionable organic matter, all the chemists agree that in Thames water taken from the present source and properly filtered, all such matter has disappeared, and that the resulting compounds, such as nitrates, &c., remaining therein are innocuous and harmless.

Having carefully considered all the information we have been able to collect, we see no evidence to lead us to believe that the water now supplied by the companies is not generally good and wholesome.

215. The only point raised against the Thames water on the ground of organic contamination is of a less positive character; it is said that water which has been once contaminated with sewage may still contain undecomposed organic matter, which, though inappreciable by the most delicate chemical tests, may still exercise prejudicial effects on the human system.

The strongest form of this objection has reference to some opinions now prevalent, that certain forms of disease, such as cholera and typhoid fever, are propagated by germs contained in excremental matter; and it is conceived possible that when matter of this kind once gets into streams, these germs may escape destruction and long preserve their dangerous character. It is said that no process is known by which such noxious material can be removed from water, and therefore it is argued that water which has at any time been contaminated by sewage is thenceforth unsuitable for domestic use.

These opinions have been advanced by many eminent men of science; they are worthy of respectful attention, and ought to operate as a constant stimulus to the most searching examination of the state of the water; to the improvement of the modes and means of scientific analysis; and to the diligent collection of medical data as to the effect of the waters upon the public health. But we cannot admit them as sufficiently well established to form any conclusive argument for abandoning an otherwise unobjectionable source of water supply.

216. We may also expect that the state of the Thames and the Lee will be very much improved by the exclusion from them of all sewage and other offensive matter, in accordance with the provisions of the Acts of 1866 and 1868. And it is worthy of consideration whether these provisions should not be extended higher up the tributary streams, so as to exclude all possible sources of noxious pollution.

217. We are of opinion that, when efficient measures are adopted for excluding the sewage and other pollutions from the Thames and the Lee, and their tributaries, and for ensuring perfect filtration, water taken from the present sources will be perfectly wholesome, and of suitable quality for the supply of the metropolis.

218. The analyses made specially for us of the waters in the various parts of the Thames basin are, we conceive, of great interest and value, and will be very useful as data for comparisons of the state of the river at future times. The result shown by them that the present point of intake is the best that could be chosen in the whole course of the river, is peculiarly important and satisfactory.

PART V.

REMARKS ON VARIOUS POINTS BEARING GENERALLY ON THE SUBJECT OF THE METROPOLITAN WATER SUPPLY.

Section I.

ON THE QUANTITY OF WATER LIKELY TO BE HEREAFTER REQUIRED FOR THE SUPPLY OF THE METROPOLIS.

219. The quantity of water that is likely to be hereafter required for the metropolis forms a prominent element in the consideration of any plans of supply, and we propose to devote a few remarks to the elucidation of this subject.

This quantity will obviously depend on two elements—

(*a.*) *The estimated future population, and*
(*b.*) *The quantity to be allowed for each individual.*

(*a.*) As to the estimated future Population to be provided for.

220. The population of London embraced within the limits of the Registrar General's district (see map Appendix AW.), was given for the middle of the year 1867 at 3,082,372 persons.

The number of persons estimated to have been supplied by the companies in that year, as given in the table in Part III. of our Report, amounts to 3,100,000. The districts supplied have a somewhat wider range than that of the Registrar General, as they extend farther into the suburbs; but on the other hand, it is probable that some portions of the population may not be included within the companies' returns.

221. In reasoning upon the probable number of persons to be hereafter provided for, Mr. Bateman states as follows:—

"Will you give us, in the first place, the population of the metropolis in the year 1861?—According to the population returns for that year the population within the district of the Metropolitan Board of Works was 2,803,034 persons. 3–4.

"What is the present population?—The present population, taking the rate of increase at which the metropolis in recent years has been increasing, is upwards of 3,000,000 by estimate. Dr. Letheby, in December 1866, gives the population at 3,067,000 in round numbers. The rate of population has been as follows: it has trebled since the beginning of this century, it has doubled itself in the last 40 years, and it is now half as large again as it was 20 years ago; therefore, at the same rate of increase, in 20 years, it will be half as large again as it is now, and will amount to 4,500,000 persons. I believe that that will scarcely represent the whole population which may be expected to reside in the immediate neighbourhood of London at that time, because the suburbs of London beyond the area included in the district of the Metropolitan Board of Works are so rapidly increasing that they may be taken as forming a part of the metropolis, and ought to be considered with reference to any supply of water."

He gives further explanations of his views on this point, and adds:—

"In 1856 the supply was at the rate of 28 gallons per head per day, in 1866 it was at the rate of 31 gallons per head per day, and in 1867 it was at the rate of 32 gallons per head per day. If you take 32 gallons per head per day as the consumption, and estimate the population in 1877, nine years from the present time, at 3,650,000 persons, which it would amount to at the rate of 1·73 per cent., you will want 117,000,000 gallons a day. If you take the increase at the rate of 2½ per cent., you will want 127,000,000 gallons a day at that time; and if you take it at 3 per cent., which with all deference I think ought to be what you should take it at, you will want in nine years from the present time 132,500,000 gallons a day. Judging from the experience of all the places that I know, I think that is about the right amount to take, and my own belief is that when you get water which can be supplied by gravitation, when you include everybody as you ought to do upon the principle which I have laid down, and compel them to pay for water, and therefore give them an inducement to take it and use more than they have done, when you have converted every privy into a water-closet, and when you have water of the softness of Welsh water, in which case you would sell as much again for trade purposes as you do now, that is an under-calculation instead of an over-calculation, and my belief is that before nine years are over you will want more than 130,000,000 gallons a day. However, I have assumed 130,000,000 gallons, because that happens to be the scale on which I devised these works when I first laid them before the Commission, and that seems to me to be the quantity which may be required about the time at which they could now be executed." 6583–6.

In about 12 or 13 years from the present time he estimates that 170,000,000 gallons will be required, and ultimately 230,000,000 gallons; but he extends his estimates to the provision of 300,000,000. 6632–54.

Mr. Hawksley, on the other hand, does not agree to the probability of the increase continuing at such a rapid rate. He says:

502. "Of course you must add to the present population, and that is a very difficult question, because it is quite impossible to take it that London should increase at the rate it has recently done; we know indeed by the census tables of this kingdom as well as of others that the rate of increase is declining. In all countries the rate of increase attains a certain maximum and after that it declines. Put it as it was in England at the period of the greatest increase; the increase I think was a little over 2 per cent. per annum throughout the kingdom in general. Then it declines and it will go down to $1\frac{3}{4}$ per cent. Then in future periods it will be $1\frac{1}{2}$ per cent., and so on till it comes down to a more moderate rate of increase. In England we have had a wonderful stimulus by the inventions which have been made; the introduction of the steam engine and railways in particular, and the enormous development of our manufacturing power, contributed for a certain period to a most rapid increase of the population, but the increase will not, in my opinion, continue at the same rate; nor is the supposition warranted by the statistical facts gathered in England itself and in other countries as well."

The Government Commissioners, Captain Galton, Mr. Simpson, and Mr. Blackwell, who reported in 1857 on the Metropolitan Main Drainage, considered the question of the probable increase of population for which sewage should be provided, and they estimated the prospective population in the metropolitan districts at 3,578,000 as compared with 2,362,000 in 1851. They also added 401,000 for a suburban area beyond the limits, making a total prospective population of nearly 4,000,000 for which the sewage plan should be laid out.

222. With the view of aiding in the elucidation of this subject, we have had prepared, from the Census Returns, the four diagrams marked Appendices AL, Nos. 1, 2, 3, and 4 respectively.

Diagram AL (1) shows the increase of the population of the metropolis from 1801 to 1861, distinguishing the increase from excess of births over deaths, and that due to immigration. Diagram AL (2) shows the manner in which the increase of the metropolis has been distributed among the persons of different occupations in life. It will be seen that the increase due to immigration is very much the larger, being in the 60 years 1,287,200 as compared with 557,920. It appears somewhat doubtful whether this source of increase will go on as fast as heretofore; it has already diminished from $17\frac{3}{4}$ per cent. in the first 10 years of the period to 8 per cent. in the last 10 years; and if it should decrease further it will prevent the continuance of the increase of the metropolis in its former ratio. The diminished immigration, which probably consisted largely of bread-winning adults, exhibits a check to the increasing means of employment; and this is also borne out by the diminished rate of increase among the industrial classes, which was between 1841 and 1851 nearly 51 per cent., but was little over 11 per cent. between 1851 and 1861. This does not lead us to anticipate an increase in the population of London similar to that of past years.

Diagram AL (3) shows the increase as distributed among the districts of the various water companies, and AL (4) among the various metropolitan districts. This last diagram also gives the population *per square mile* of area in the different districts and parishes. It must be considered, that with the present great accommodation of suburban railways, which will doubtless further extend, the population will be likely to increase principally in the districts lying within a few miles of London, and it will undoubtedly be necessary, as Mr. Bateman suggests, that these districts should be properly provided for as a part of the system of the metropolitan supply. We believe all the companies are alive to this prospect, and have been arranging their plans to meet the wants of these districts as they gradually arise.

223. It is impossible to calculate with any exactness to what extent this increase will go on in any given number of years; but from the whole of the above data we have endeavoured to estimate what increase would be probable, and we are inclined to think that Mr. Bateman's estimate of $4\frac{1}{2}$ millions as the future population to be considered is reasonable, although we should allow more time than he does for this population being attained. In our calculations of quantity, we shall, to be on the safe side, assume an ultimate future population of 5,000,000.

(*b.*) Quantity of Water to be allowed for each Individual.

4038. 224. The quantity of water, per individual, necessary to be supplied in any particular town appears to be very difficult to reduce to any definite rule. It is found that on an average about 10 gallons per head per day are sufficient for ordinary domestic requirements, including waterclosets; but to this have to be added large supplies for street watering, flushing sewers, &c. &c., and for trade purposes and other large

consumption, which in the case of London have been estimated at another 10 gallons. Then in addition to these there is considerable waste, often amounting to, or even exceeding, the whole domestic supply.

225. The following is a resumé of the evidence we have received on this point:—

Mr. Bateman states that the quantity varies very much, according to the character of the place and the class of inhabitants; it varies from 15 to 16 gallons a head a day to 50 gallons. Hence each town and city ought to be taken with reference to its own existing circumstances, and what the probabilities are of the supply being greater or stationary.

He takes the present London supply as equal to about 36 gallons per head per day, and he thinks that this, or even 40 gallons (looking to the constantly growing consumption of water), ought to be the least taken in any estimate of supply for the metropolis. 6–20. App. E.

He states that in Glasgow the consumption is 50 gallons, including, however, a very large waste; and that in Manchester the gross quantity supplied is 21 or 22 gallons per head, of which about one-third is for trade purposes; but as baths and waterclosets are very sparingly used there, this does not afford a safe criterion.

Mr. Duncan states that for a large town, where sufficient care is taken to prevent waste, 30 gallons per head per day would be about the right quantity; but he thinks it will go on increasing in future to probably about 45 gallons, which he would take as the measure of a future supply. 2365–74.

Mr. Hawksley says that in his view 25 gallons would be safe; but if this were extended to 30 gallons he thinks there is no doubt whatever that that would be a superabundant quantity. He considers that 30 gallons per head would be quite a safe calculation for the probable necessity of a population like London—more than enough; including all trades, all waterclosets, stables, incidental causes of consumption, and all household consumption and street watering. 2502. 5088–92.

Mr. Simpson estimates that, looking forward to a few years to come, about 30 gallons per head would be a sufficient provision for the population of London, including all public sewers. 4718–21.

Mr. Hassard states that the Dublin Waterworks are estimated to supply 40 gallons per head, with provisions for a larger quantity if required. He considers that the estimate for London ought to be 50 gallons. 551–62. 865.

Mr. Rawlinson is of opinion that half the water now supplied in London is wasted, *i.e.*, is not used for any useful purpose. Allowing for waste, he conceives 30 gallons a head is sufficient. 1408–11.

Mr. Muir, after much investigation, has found that 10 gallons a day are ample for ordinary domestic purposes, and 20, including all other requirements, for such a city as London. The difference between this and 30 gallons, the present consumption, is due entirely to waste. But he adds,— 4058–64.

"I think a great deal more might be done than is done now for the prevention of waste. The companies, and the New River Company I may say especially, have attempted to check waste to some extent for the sake of the consumers, (for the waste of one set of consumers is very injurious to another, who may be upon a higher level,) and they have succeeded in some measure in reducing waste, without in the least degree stinting the proper supply of their tenants."

Mr. Greaves gives an account of some special investigations on this point which lead him to the belief that the whole population of London ought to be very well satisfied with 24 gallons per head. The results are as follows:— 5143–54.

"Can you give the Commission the result of that?—I can give 15 cases of streets. One street averaged 306 gallons per house per day; the number of inhabitants I do not know; I have taken it per house. Those quantities were determined by the insertion of meters on the supply pipe of the street without any particular information or instruction to the people that they were being metered, but merely as a source of information for ourselves.

"What would you take as the average population of each house?—7½ I should think. No. 1 street comes out at 306 gallons per day; No. 2 at 329 gallons; No. 3 at 283 gallons; No. 4 at 132 gallons; No. 5 at 90 gallons; No. 6 at 96 gallons; No. 7 at 148 gallons; No. 8 at 45 gallons; No. 9 at 87 gallons; No. 10 at 194 gallons; No. 11 at 78 gallons; No. 12 at 358 gallons; No. 13 at 146 gallons; No. 14 at 73 gallons; and No. 15 at 37 gallons."

The average of the whole was 160 gallons per house, or 21 gallons per head.

Mr. Beardmore considers that, including waste, which is enormous, the quantity required for London per head, including trade and public supplies, would not be less than 35 gallons per head per day. 3326–7.

Mr. Dale allows 30 gallons per head for all purposes. The supply at Hull is 32 gallons. 1095–6.

927–30. 943–5. Dr. Letheby considers 20 gallons per head for all purposes a good and sufficient supply. All beyond is wasted.

226. We have endeavoured to collect data as to the supplies in different towns, and Mr. Bateman and Mr. Simpson have communicated to us the particulars given in the tables printed in Appendix AM. It will be seen, however, that the quantities per head for the total supplies vary enormously in the different cases, from 14½ gallons at Norwich to 53 at Glasgow, showing that every case must be judged by its own circumstances.

We conceive, therefore, that the only way to arrive at an estimate for the metropolis which shall have any pretensions to be relied on, is to reason from the present experience, making such alterations as may seem to be necessary for the future.

227. The quantity of water supplied per head in any town may be estimated in two ways; *i.e.*, by dividing the total quantity either among the whole population, or among that portion of them only who take the water, the latter number of inhabitants being frequently much less than the former. In the following table we have endeavoured to give the quantity according to both these methods:—

QUANTITY of WATER supplied to the Metropolis at different dates.

	1829.	1849.	1856.	1867.
Average daily quantity of water supplied - - -	29,000,000	44,383,129	73,376,860	98,600,248
Number of houses and tenements supplied by the companies	177,000	267,305	319,213	441,442
Estimated number of inhabitants therein - - -	1,239,000	1,871,135	2,234,491	3,100,000
(N.B.—Where this item is not given in the returns it is obtained by assuming seven inhabitants to each tenement supplied.)				
Daily supply per head to inhabitants taking water from the companies - - - - - - -	23·3	23·6	33	31·8
Total population of the metropolis - - -	1,572,000	2,280,000	2,583,000	3,082,372
(N.B.—This has been filled in by proportionate interpolation from the decennial census returns.)				
Proportion of whole population supplied with water -	79	82	86	100
Daily supply per head on the whole population - -	18·3	19·4	28·5	32

It will be seen that in 1828 only about 79 per cent. of the inhabitants were supplied by the companies, the remainder procuring their supplies by shallow wells and pumps from the superficial gravel on which London stands. As this source has become worse, by the increasing contamination of the water from underground pollutions, it has been gradually abandoned, and the proportion of persons taking water from the companies has been gradually rising to the present time. It must be remembered, however, that the number of inhabitants in each tenement is merely an estimate, and the districts included extend in some cases beyond the limits of the census returns.

As regards the quantity supplied per head, the table shows that, estimated on the whole population it has increased from about 18 gallons in 1828 to 32 gallons in 1867;—while estimated by the number of persons actually taking water from the companies, it has increased from about 23 to 32 gallons.

228. This is no doubt a considerable increase, but we think it may be accounted for in a way that will not warrant the expectation of its continuance to any considerable extent. During the last 20 or 30 years very great advances have been made in sanitary arrangements; the introduction of waterclosets into houses, the much more frequent use of private baths, and a general advance in domestic cleanliness, have all tended largely to increase the quantity demanded. The companies have met the demand liberally, and all the upper and the middle classes of London may be said to be at present so plentifully supplied with water that further augmentation would be only waste. In regard to the lower classes, there is, no doubt, much sanitary improvement still to be effected, and much more useful application of water still to be promoted; but it is probable

that the improvement will have a tendency rather to check the waste than to increase the supply.

We are not aware that the requirements of trade, or the quantities used for municipal purposes, are likely materially to increase in a larger proportion than the increase of population, so that no variation on this ground need be taken into account.

The only remaining element of change likely to occur would be the introduction of the system of constant service. This would probably not materially affect the quantity of water actually used, but it would have a considerable influence on the quantity supplied, by affecting the amount of waste.

It has been found that where the system could be carried out perfectly, with suitable house arrangements and under efficient control, so far from wasting water it has considerably economized it; but considering the great difficulties that must be encountered in making the change under such disadvantages as will be experienced in London, there is reason to fear that, with every precaution, a considerably increased loss of water will at first be suffered. It is impossible to foretell to what extent this loss may go, or how long it will be before it can be subdued; all will depend on the caution with which the change is made, and the efficiency of the control exercised. But it is to be hoped that before many years after the constant service is commenced, the supply may be brought down again to its normal quantity. And it must be recollected that as the population extends, all new supplies, being adapted (as they ought to be even now) for the new system, will be on the most economical plan. And looking forward further still to the time when long experience shall have been gained of the plan, ample time allowed for making all improvements and changes, and a rigid supervision introduced, it would not be too much to expect that a considerable reduction of the present waste may be effected, and the supply be brought down much nearer than at present to the quantity beneficially used. 2561.

Estimate of Quantity.

229. If these views are correct, we may give the following as an approximate estimate of the quantity to be provided:—

	Gallons per day.
The present supply is, say, for 3,000,000 of population, at 33⅓ gallons per head, equal to	100,000,000
Assume the population to have increased to 4,000,000, and at the same time the additional waste due to the new introduction of the constant service to have increased the supply to 40 gallons per head, equal to	160,000,000
By the time the population has increased to 5,000,000 we may hope that the allowance may be reduced again to 35 gallons, which would give	175,000,000
Or for the maximum summer consumption, say	200,000,000

which we consider the highest demand that need be reasonably looked forward to for the metropolitan supply.

Section II.

PROVISIONS AND PROSPECTS OF THE VARIOUS COMPANIES FOR THE FUTURE.

230. Having thus arrived at an estimate of the future quantity of water which may be required for the metropolis, we have thought it right to inquire what provisions the various companies have made for increasing their supplies as the increasing demands arise. We had previously addressed, to the five companies now drawing water from the Thames, a letter on this subject, which is printed, with the answers to it, in Appendix L.; to these have been added further information given by the engineers of the various companies at our request; and the following statements will, we believe, express the companies' own estimates of their positions and prospective capabilities.

231. The *New River Company* state that from their present sources, and with their existing works, they can obtain the following quantities of water:— App. BF.

	Gallons per diem.
Average flow of the Chadwell Spring - - - - - - -	3,500,000
Quantity which the New River Company are authorized to take at all times from the River Lee, through their gauge at Hertford - - - - -	22,500,000
Additional supply from gathering ground at Cheshunt, &c. - - - - -	500,000
Quantity obtainable from six existing deep chalk wells, upwards of - - -	8,000,000
Water collected in ponds at Hampstead and Highgate, and distributed through separate mains for watering roads and other non-domestic purposes - - -	500,000
Total - - -	35,000,000

In addition to this, there is the produce of a new well now in preparation at Wormley, and also the quantity of unfiltered water that might be drawn from the Thames through separate mains for street watering, &c.

The company are further entitled, by the "River Lee Water Act" of 1855, to increase their supply from that river by storing flood waters, and they believe that under these powers a considerable further addition may be obtained, the New River being capable of conveying twice its present flow. But they have not thought it necessary to mature any plan for this purpose.

The *East London Company* have felt the necessity of largely increasing their powers of supply. They have, like the New River Company, power to store flood water in the River Lee, and in 1867 they obtained an Act to make a considerable increase in their present reservoirs; but they have preferred, as a larger and more certain measure, to go also to the Thames, and they obtained, in the same year, an Act (30 & 31 Vict. c. 148), enabling them to draw from this source a quantity of 10,000,000 gallons per day.

The works authorized under this Act are now in course of construction. The water will be taken from the Thames at Sunbury, about a mile and a half above the intake of the other companies at Hampton, and from this point the water will be lifted to a station at Hanworth, where it will be filtered. It will then be pumped through an iron main, 18 miles long and 36 inches diameter, into a service reservoir on high ground at Hornsey Wood Hill, and thence delivered either into the district for use or to replenish the increased storage in the valley of the Lee.

It is expected the works will be finished in 1871, and that they will cost, under the two Acts, about 450,000*l*. The capabilities of this company may then be estimated at about 30,000,000 gallons per day.

The *Chelsea Company* are empowered to draw from the Thames a quantity of 20,000,000 gallons per day; and they state (Appendix L.) they could pump, filter, and store this quantity without materially adding to their present capital. As, however, their present supply is only half this, we presume so great an increase might overtax the safe and efficient capabilities of the works, unless further mains and pumping and filtering power were provided.

The *West Middlesex Company* have also power to take 20,000,000 of gallons from the Thames. The pumping engines there are already calculated to pump 12,000,000, or more, if worked to their full power; but when this quantity is much exceeded duplicate engines would be required. A new main is already under construction from Hampton to Barnes, which, when finished, will with the present one convey the full quantity. The present reservoirs, filters, and distributing engines are equal to about 15,000,000, but land is provided for the necessary extensions. The mains from Hammersmith to the store reservoirs are of the full capacity.

The *Grand Junction Company* have power to take 20,000,000 of gallons. The present works are calculated to deliver 13,000,000, but are laid out so as easily to admit of extension. A large new covered store reservoir, to hold 10,000,000 of gallons, is now being constructed at Camden Hill.

The *Lambeth Company* are empowered to take 20,000,000 of gallons. They are now duplicating their main from the Thames to Brixton, which, with the former one, will safely deliver this quantity; and the additional pumping, filtering, and reservoir power will be added as required. The works have been laid out, and land provided, with a view to a still larger increase.

The *Southwark and Vauxhall Company* have power to take 20,000,000 of gallons. The works already in operation are capable of supplying about 15,000,000 gallons, but the company are now constructing additional engines at Hampton, with large new reservoirs and filter beds, and are laying down a new line of 30-inch main; and when these works are finished, the whole quantity of 20,000,000 gallons may be delivered when required.

The *Kent Company* state that their present wells will supply 14,000,000 of gallons per day, and that with their present machinery they could raise 10,000,000. One of the wells at Charlton is a duplicate, not yet used. They are now sinking another well and erecting new engines at Deptford, where more water is wanted. 6141.

Summary.

232. It appears from the above data that the various companies represent themselves as being prepared, with their present legal powers, and with only moderate additions to their present engineering means, to supply the following quantities of water:

	Gallons per day.
New River	35,000,000
East London	30,000,000
Chelsea	20,000,000
West Middlesex	20,000,000
Grand Junction	20,000,000
Southwark and Vauxhall	20,000,000
Lambeth	20,000,000
Kent	say 15,000,000
Total	180,000,000

Which is very little short of the quantity we have estimated as the highest demand that need be reasonably looked forward to for the metropolis, but which is still far below the limit of the quantity capable of being furnished from the Thames basin.

Section III.

ON THE SYSTEM OF CONSTANT SERVICE AT HIGH PRESSURE.

233. We have explained in Part III. of our Report that in the distribution of water in London, the water is not constantly laid on to the mains serving the houses, but is only supplied to them during an hour or two each day; this is what is called the "intermittent service" system, in contradistinction to that of "constant service," in which the service pipes are always charged under pressure, and the water may be drawn from them at all times by simply turning the taps in the houses.

234. This constant service system is now adopted in many country towns, and it has obviously many advantages over the other plan. It allows the water to be drawn always fresh from the main, free from the pollution often acquired in dirty receptacles (an evil of great magnitude among the poorer classes), and it ensures supplies at all times independent of cistern storage. It is also a great advantage to have the mains always charged in case of fire, without waiting for the intervention of the turncock, as on the intermittent plan.

Independently, however, of the advantages to the consumers, the constant service plan would seem to be so much more simple and easy to work than the intermittent (which requires much complexity of construction, and trouble of management), that one would think the companies would have adopted it for their own sakes, were there not good reasons to the contrary. In the various discussions that have taken place on the metropolitan water supply, the adoption of the system has been strongly urged; but the proposition has been met by statements of the causes which have led to the adoption of the intermittent plan, and of the difficulties that would arise in attempting to introduce the rival one.

235. In order to make the subject clear we may state at once what these difficulties are; and as far as we can learn, they appear to be five in number.

1. In the first place it is alleged that there is great leakage from the fittings in the houses, producing a waste of water which, though it can be met when it lasts only an hour or two a day, yet if allowed to go on for the whole 24 hours would amount to such an enormous quantity that the supply could not be kept up with the present means or at the present cost. This leakage always takes place to some extent even in the better class of houses, by inattention to the state of ball-cocks, watercloset apparatus, &c.; but it is in the poorer districts, where through carelessness and dishonesty it is impossible to keep the fittings in a respectable condition, that the chief difficulties arise.

2. It is also alleged that assuming all the fittings to be in good order, their strength, particularly that of the lead pipe, though suitable for the small pressure of the intermittent supply, would not be sufficient for the greater strain necessarily induced by constant service at high pressure.

3. The habits of domestic establishments lead the inmates to draw their larger supplies of water at one particular time of the day. During the morning hours the consumption is double the average. Now on the intermittent system this variable draught comes upon the store cisterns, and does not interfere with the power of distributing the quantity pumped uniformly over the day; but under the constant system it would come directly on the mains, and the increased draught at a particular time would lead to much inconvenience. For such of the companies as have no store reservoirs, but are obliged to supply entirely by pumping, the increased draught would require a much greater pumping power to be in readiness, a large portion of it, however, being used only for a short time in the day.

4. This greater draught at a particular time, when it occurred at low levels, would further have the effect of reducing the pressure in the mains and services to such an extent as to render them incapable of supplying at the same time the higher parts of the districts. The leakage also would powerfully contribute to this effect, and thus it would become necessary generally to increase the dimensions of the mains and service pipes throughout the entire metropolis. It is a part of the present system, enforced on the companies by Act of Parliament, to supply the better class of houses up to their highest floors; and as many of these houses are of great height, and stand on elevated ground, a great pressure is required for this purpose. Under the intermittent system this can easily be arranged, but under the constant system these high services would be entirely at the mercy of the draught going on at lower levels. And even in the same building no water could be had on an upper story while lower ones were drawing.

5. In case of any repairs or alterations to the mains, or of any accident whatever interrupting the flow in them (instances of which are said to be of almost daily occurrence in some parts of London), the whole district served by those mains must under the constant system be deprived of water, whereas under the intermittent plan the house cisterns keep up the supply. For this reason it is urged that it is advisable to retain the cisterns, even where constant supply is given, whereby one of the advantages alleged in its favour is done away.

236. Before remarking on the weight to be attached to these objections, we may review what has already been done in the matter, and state the evidence given before us thereon.

Nearly a quarter of a century ago it seems to have been established that on public grounds the system of constant service was the right one, for at the time of the passing of the "Waterworks Clauses Consolidation Act" in 1847 (10 Vict. cap. 17) the following provision was introduced:—

"XXXV. The undertakers shall provide and keep in the pipes to be laid down by them a supply of pure and wholesome water, sufficient for the domestic use of all the inhabitants of the town or district within the limits of the Special Act, who, as herein-after provided, shall be entitled to demand a supply, and shall be willing to pay water rate for the same; and such supply shall be constantly laid on at such a pressure as will make the water reach the top story of the highest houses within the said limits, unless it be provided by the Special Act that the water to be supplied by the undertakers need not be constantly laid on under pressure."

This Act was intended to be incorporated into all Waterworks Bills thenceforth introduced, and it became therefore the law of the land that the constant service system should be applied in all new works, unless special reasons could be shown for its inapplicability.

237. The Board of Health, in their report of 1850, strongly urged that the metropolis should be brought under this system, putting on record the following opinions on the point:—

"That the practice of intermittent distribution occasions, in the case of the better description of houses, the retention of the water in cisterns and butts; and in that of the poorest classes, in tubs, pitchers, and such other vessels as can be obtained; and as a consequence of such retention the water imbibes soot and dirt, and absorbs the polluted air of the town, and of the offensively close, crowded, and unhealthy localities and rooms in which the poor reside."

"That the annual cost of the construction and maintenance in repair of cisterns, and their supports and connected apparatus, in the houses of the middle and wealthier classes, often exceeds the annual water rate."

They also add the following remarks:—

Many practical difficulties have been urged against the substitution of the constant for the intermittent system of water supply in the metropolis, we have particularly examined into the working of the constant system in towns where it is established, and in some of which it has been in operation for 15 and 20 years, and we find—

That the waste of water is so far less, instead of greater, under the system of constant supply, that although the inhabitants have unlimited command of water, and use what they please, though the actual use of water by the inhabitants is greater, the quantity delivered by the companies is less, frequently less by one half, in consequence of there being less waste from the more perfect delivery.

That the water under the system of constant supply is delivered purer and fresher, of a lower temperature in summer, and that it is less subject to frost in winter.

That the inconveniences apprehended from the interruption of supply during repairs and alterations are never experienced, the work being executed under such simple precautions that no complaint has ever been known to have been made on this account.

That the interruptions of supply which are so constantly experienced on the intermittent system from the waste in the lower districts, from the neglect of turncocks, from limitation of quantity, from inadequate or leaky butts and cisterns, or from deranged ball-cocks, are scarcely ever known on the constant system.

That the system of constant supply admits of great economy in pipes, as they may, under that system, for the most part, be considerably smaller, and, not being subject to the violent hydraulic jerks of the intermittent system, are less liable to burst.

That the pipes for the house service may not only be considerably smaller and cheaper, but that the cisterns and apparatus connected therewith, which in the smaller class of houses now cost more than the whole public portion of the works, may be entirely dispensed with.

238. The subject was warmly discussed before the Committees on the Waterworks Bills in the Sessions of 1851 and 1852. The Government wished to carry out the constant service system, but were met by arguments urged by the companies against it, and the result was a sort of compromise, by the introduction into the Act of 1852 of a clause compelling the companies to give a constant service to any district when required by four-fifths of the inhabitants, on its being shown that the pipes and fittings in the houses were in a proper condition to receive such supply. The following is the clause:—

"XV. After the expiration of five years from the passing of this Act, every company shall, subject to the provisions of the Special Act relating to such company, provide and keep, in the district mains already laid down or hereafter to be laid by them, a constant supply of pure and wholesome water sufficient for the domestic use of the inhabitants of all houses supplied by such company, at such pressure as will make the water reach the top story of the highest of such houses, but not exceeding the level prescribed by the Special Act of such company: provided that no company shall be bound to provide a constant supply of water to any district main until four-fifths of the owners or occupiers of the houses on such main shall by writing under their hands have required such company to provide such supply, nor even upon such requisition, in case it can be shown by any company objecting to the same that more than one-fifth of the houses on such main are not supplied with pipes, cocks, cisterns, machinery, and arrangements of all kinds for the reception and distribution of water, constructed according to the regulations prescribed by the Special Act or by this Act, or which any company, with the approval of the Board of Trade, may from time to time make in that behalf; and after any such requisition as aforesaid shall have been delivered to the company, it shall be lawful for the surveyor, or any other person acting under the authority of the company, between the hours of nine of the clock in the forenoon and four of the clock in the afternoon, to enter into any house or houses on such district main, in order to ascertain whether the pipes, cocks, cisterns, and machinery of such house and houses are so constructed as aforesaid; and provided also, that any company may, with the consent of the Board of Trade, suspend the giving of such constant supply, or give the same in succession to the several districts of such company or to any parts of such districts as may be found to be convenient; and provided that it shall be lawful for the company, after due notice, to abstain from supplying, or to cut off the communication pipes, and withdraw the supply of water from any house whereof the pipes, cocks, cisterns, machinery, or arrangements as aforesaid shall not be in conformity with such regulations; provided that neither the Kent Waterworks Company nor the Hampstead Waterworks Company shall be required to give such supply at any height exceeding one hundred and eighty feet above Trinity high-water mark, nor the East London Waterworks Company be required to give such supply at any height exceeding forty feet above the level of the pavement nearest the point at which such supply shall be required."

It would appear that the companies convinced Parliament of the validity of the fifth objection we have given, namely, as to the necessity for the retention of the cisterns under the constant service system, for the following provision was added in clause 22:—

"Whenever water shall be constantly laid on under pressure in any district main, every person supplied with water under pressure by any company through such main shall, when required by the company, provide a proper cistern or other receptacle for the water with which he shall be so supplied."

And then follow provisions as to ball-cocks and fittings, and prevention of waste, &c.

We believe that cisterns are retained to a considerable extent in Manchester and many other towns where constant service is given.

239. The House of Commons Committee of 1867 devoted particular attention to this subject, and as they took a large mass of evidence, embodying the most recent experience on both sides, it may be useful to present at length the conclusions at which they arrived, as set forth in their report:—

67. The Act of 1852 is so framed that the introduction of any constant supply depends upon its provisions relating to the preparation of plans, and the proceedings consequent thereon, but these provisions have been too difficult of application to be carried into effect in a complete or satisfactory manner. With some trifling exceptions, therefore, the metropolis is now supplied by the water being turned on for a short time in each day, except Sundays, when no supply is given to the larger part of the metropolis. The occupiers are left to obtain and store as much of the supply as they may desire, or as the condition of their houses will admit.

68. The use of cisterns for the purpose of storing water for consumption is probably a more fertile cause of impurity than any pollution of the river from which the water is drawn. Decaying animal or vegetable bodies, or other impure matter, may easily find their way into a cistern, and are more likely to engender disease than any impurity existing in the water before it flows into the cistern. In well-regulated houses the cisterns are of course constantly drawn dry, and properly cared for; but as cleanliness decreases, it is found that the cisterns are allowed to become more foul until the lowest state is reached, when the water is stored in tubs and otherwise, under the most disgusting conditions, which cannot but be injurious to health, and a cause of the diseases which are found to prevail in the worst regulated parts of London. On the other hand, an intermittent supply of water without cisterns not only deprives the inhabitants of the supply they ought to receive, but from the want of adequate storage it is kept in pails and other small receptacles, in rooms and places where it is liable to much contamination.

69. For these and other reasons, which will be found in the Evidence, and in the paper of Dr. Farr, No. 7 in the Appendix, and the report of Captain Tyler, which are full of interest, your Committee have come to the conclusion that the Act of 1852 has failed to secure for the inhabitants the advantage which they ought to have long since enjoyed of a well-regulated supply of water in their houses for domestic purposes; your Committee therefore recommend that the Act should be amended by providing that every company should afford a constant supply of water to each house, so that the water may be drawn direct from the company's pipes at all times during the 24 hours, with the exceptions herein-after mentioned.

70. It is right, however, to observe that this recommendation cannot be carried into effect unless adequate provisions are also made to prevent the waste of water which may arise from its being constantly laid on in every house. To determine how far water may be and is in fact now wasted in the metropolis, much evidence has been given which is deserving of notice.

The Committee go on to investigate this matter, and come to the conclusion that out of 78½ millions of gallons supplied daily, about 17 millions are wasted. They then remark:—

75. From experiments made on several occasions in the metropolis, it has been found that where the supply was suddenly changed from the present intermittent system to a constant supply, without any alteration of the arrangements in the houses, there was an enormous waste of water. The experience derived from changes made from an intermittent to a constant supply in other towns, without suitable arrangements within the houses, leads to the same result.

76. Your Committee have therefore endeavoured to ascertain the precise causes of this waste, and the means by which it may be obviated.

77. With regard to the constant direct supply of water to a tap in the house, it appears that no waste is likely to occur if it be so placed and arranged that waste cannot take place without producing inconvenience, which will be immediately felt by the person permitting the waste, and that there are no real difficulties in fulfilling these conditions.

78. All other modes of supply afford opportunities of waste, which it is not so easy to prevent. The ordinary cistern is so liable to occasion waste, that it has been found requisite in other places to lead the waste-pipe into some exposed position, where any flow from it can be immediately detected. It would no doubt be necessary to make this alteration when a cistern is maintained, but as it would be easy to substitute a direct service, without the intervention of a cistern, except for hot-water services or closets, no difficulty need be apprehended on this account.

79. But with regard to the supply of waterclosets, it has been shown that in consequence of the practice of allowing the water to flow through them uninterruptedly for long periods, instead of merely flushing them, they are a frequent cause of great waste, which cannot be detected; there appears, however, to be no difficulty in guarding against this by making such arrangements for flushing, that the water cannot flow on continuously for an unlimited period.

80. It has indeed been objected by some of the witnesses, that it will be found impracticable to maintain any flushing apparatus in proper order in houses frequented by the most negligent people, and that it would be better in these cases to leave them to draw water and flush with a pail. If this were a question affecting the individuals only, such an arrangement might be tolerated, but the health of the public being greatly concerned in the rapid removal of all matters which may either engender the forms of disease, for the most part infectious, found in ill-regulated habitations, or may tend to spread such disorders when they arise from other causes, your Committee are of opinion that the introduction of a flushing apparatus where no water service now exists ought to be imposed on the owner of every house, without prejudice to his right to recover the cost from the tenant, if the latter be under an obligation to incur the expense.

81. The other special services provided with cisterns will be of a limited character, under conditions where the waste is not likely to be considerable, and it will be sufficiently guarded against by the arrangements recommended.

82. It has also been objected by some of the witnesses that there is no remedy for one of the chief causes of waste in certain localities, which is to be found in the tendency of evil-disposed persons to take away all fittings of brass or copper.

83. Your Committee have, however, been informed that it is not impossible to remove much of this temptation by reducing the present use of copper and brass in such fittings; but as the removal of the fittings undoubtedly causes great waste of water and loss to the companies, as well as great inconvenience and injury to the public, your Committee are of opinion that the unlawful removal of fittings should be made a specific offence, punishable summarily with imprisonment, and that the sale of such fittings, if marked with some certain initial letters, should be placed under the same restrictions as the sale of stores with the mark of the Crown on them, by which the unlawful traffic in such fittings would be repressed.

84. It has been further objected, that if the constant supply were laid on in each house, there would be great danger of the house pipes bursting in frosty weather; but it has been stated in reply, that this cause of danger may be easily obviated by the water being turned off at the stop-cock at night, and the house pipes being emptied by drawing the water off at the lowest tap in the house. This precaution is so simple as to render the objection undeserving of further consideration.

85. It has been urged by the water companies that a constant supply would endanger the pipes which have been laid down by the owners of houses between the house and the pipes of the company, called communication pipes; but as this would depend upon the arrangements which the company might think fit to make to regulate the pressure or height of the head of water supplied, which would involve much interference with the operations of the company, your Committee recommend that all the communication pipes under the

streets and pavements, up to and inclusive of the stop-cock, if any therein, should be vested in the company, and that all future communication pipes up to and including a stop-cock, should be laid down by the company at established rates of charge, at the expense of the owner, and then vested in the company, and that both those now and hereafter laid down should in future be kept in repair by the company; that it should be penal to use the stop-cock contrary to any rule of the company for cutting off the supply of water.

86. The companies would thus be left free to make their own arrangements so long as they deliver a sufficient supply of water for the upper storey of each house within the limits of height which are or may be prescribed.

87. It may be necessary to make an exception to meet the case of rows of houses of small value. It has been suggested by some of the witnesses that, for the sake of economy, these houses may be supplied by a small iron pipe, running through the houses, with a separate branch pipe and tap for each house. Your Committee recommend that in this case the companies should not be required to provide more than one communication pipe, with a stop-cock at the commencement of the through iron pipe; but it being impossible to define beforehand the occasions when this arrangement may be desirable, it should be left to the inspector to decide in each case in the event of disagreement between the owners or occupiers and the company.

88. Considering the improvements that are constantly taking place, both in economy and perfectness of construction in mechanical contrivances, and the difficulty of providing against inconvenience which may arise, your Committee do not think it desirable that any precise mode of effecting a constant house supply, or any particular kind of apparatus, should be enjoined in a statute, but that the companies should be required, in conjunction with the Metropolitan Board of Works, to frame rules, with power to alter them in like manner, for the purpose of prescribing the arrangements within the house to carry out the general principles above noticed, and that any violation of these rules should be penal.

89. To facilitate the application of these rules at the least possible expense and inconvenience to the owners and occupiers of houses, your Committee recommend that the companies should at the request of the owner or occupier provide all the fittings and apparatus required by their rules, and keep them in repair at established rates of charge, in estimating which due regard should be had to the fact that they would have to make a periodical inspection for their own protection at their own expense; and that when the fittings and apparatus are supplied by others, they should be put up in the prescribed manner, to the satisfaction of the water company, and that for this purpose standard patterns should be kept by the companies and by every local authority in the metropolis.

90. The constant supply of water to each house thus recommended will no doubt entail upon the companies a watchful supervision on the internal fittings and apparatus, for which sufficient powers are contained in the Acts above noticed; but as they will be relieved of the trouble and expense of turning on the water, which they now have to do under the intermittent system, your Committee do not consider that the companies have any valid objection or claim to indemnity on this account.

240. We may now give a summary of the evidence we have ourselves received on this point.

Mr. Hawksley says that the question of having a constant high level supply in London

Is a question of the magnitude of the pipes, and that only. The fact, as regards the piping and the constant supply, is this, that at certain periods of the day, generally between 9 o'clock and 11 in the morning, the quantity of water that is delivered is double the average quantity for the whole twenty-four hours, and consequently the main pipes must be made large enough for that purpose. Where the supply is given on the intermittent system the companies spread the delivery just as they think fit over a great number of hours, as much in one hour as in another, but on the system of constant supply they lose the command of the delivery entirely. 2257–63

2558. What is your opinion with regard to the constant supply as compared with the intermittent system which is now in operation?—The constant supply is much more beneficial than the intermittent supply *per se*, the difficulty is in changing from the one to the other.

2559. Is that difficulty in the mechanical arrangement in the pipes and taps, and so on?—Chiefly so. Of course you must have a different organization from what you have now—in point of fact there is scarcely any organization—and people must submit to the inspection of their premises from time to time, but that need not be unpleasant nor need it be frequent.

2560. Under proper inspection, assuming always that the pipes are equal to the pressure and the taps properly formed for the constant supply, do you think that the health of the public would be promoted by having their supply of water constant instead of holding it in vessels that are unsuited to the purpose?—As regards the poor I have no doubt that it would be so, as regards the middle and upper classes I do not think there is anything in that point, because we all have in our own houses admirable receptacles for water; it is quite immaterial to us.

2561. Even under proper regulations is it not your opinion that there would be a waste of water with the constant as compared with the intermittent system?—No; that I can give the fullest answer to. On the contrary, where the constant supply is well managed the waste of water is less than upon the intermittent system. I can give you a very remarkable instance, one among a considerable number, but it is so remarkable in itself that it is worth mentioning to you. A few years ago the City of Norwich Waterworks were transferred from a very old-fashioned company to a new one, by whom the system of constant supply had been accepted under an Act of Parliament, that is to say, it was imposed upon them. They tried to work it upon the old principle, and the consequence was that in a very short time the delivery amounted to 40 gallons per head per diem, and that amount of consumption exhausted all their pumping power. They could do no more, and the consequence was that they were obliged to shut off the water at night, and the company fell into a state of ruin; all their efforts were insufficient to check the waste, and the work was very nearly being closed. I was called in amongst other persons, and they obtained a very good manager, and under my advice they applied for an additional Act of Parliament to enable them to correct the fittings. With some difficulty—for the bill was opposed, as is almost always the case, for there is great jealousy about internal inspection, and so on—the bill was carried and it was put into operation, and now and for many years past, although the constant supply has been unfailingly in use, the water is never shut off, and the consumption has descended to 15 gallons per head per diem as compared with 40 previously.

5100–5. Mr. Hawksley agrees that the poor ought to have an abundant and constant supply of water, but they ought to be prevented, by proper means, from wasting it. He says,—

A constant supply, with proper regulation and proper supervision, takes less water than an uncontrolled intermittent supply; but then you must have that regulation and supervision, and if the public will not submit to the expense and will not submit to the inspection, nothing can be done for them; but if the Legislature choose to empower the companies to make it compulsory upon the landlords, through some other authority, to put everything in a proper state of repair, and keep things in that proper state of repair, there is no reason at all why the constant supply should not be granted to-morrow. I do not think that there is any company in London that would think of resisting it; but they are all in a state of alarm now, because they know perfectly well that if they were to turn on the constant supply to-morrow, probably three-fourths of the houses in London would receive no water. I should not get any water myself, it would all be draughted off into the lower districts, and run away in waste. But that is not so in the towns where there is a constant supply, and where those powers are conceded and where they are properly acted upon.

2621–2. Mr. Simpson says the constant service would be a very difficult thing to apply, unless the companies have more power; in fact it must become a question of police, or he does not see how it can be applied. He adds,—

There is an immense difficulty in dealing with the supply of the poorer neighbourhoods, and one which I confess they have never been able to surmount. Some years ago I took great pains on behalf of the Chelsea Company, who were taunted with the want of supply to the inhabitants of Westminster, to lay down pipes from the mains and have water constantly on. Immediately that was done the middle men sold all the cisterns and leaden pipes, and in the next year they refused to pay the money. They said that their tenants had not the water and that they had a right to the water, and in the course of seven years the whole of that work was destroyed which cost the company 800*l*.

We have the greatest difficulty with those small properties. It is nobody's interest to preserve the fittings, at least nobody does interfere. It is a part of the pastime of the children to injure them, and the least thing that would fetch a penny they will steal. The stealing of anything in the nature of metal goes on constantly.

4699. There are such difficulties attending it, and I hear of them on all hands, that I think it is not only a large experiment to introduce, but it would require an amount of interference almost greater, I think, than we should carry out in the metropolis.

4699. 4717. He gives a long statement to show the great difficulties which have been found at New York and in Boston, through the waste of water; and further discusses the subject as will be seen in the evidence.

4055. 4065–76. Mr. Muir, being asked whether he sees any practical difficulties in the way of constant supply, says,—

In London there are no doubt great difficulties. In a town to be supplied for the first time I think everyone would admit the desirability of a constant supply, care being taken to have everything in reference to the fittings of the houses of a proper description, and means being taken to have such supervision as would keep everything in order. The difficulty in London will arise from the amount of change required to make *old* premises ready to receive the constant supply. The position of the New River Company has always been this, that if their consumers will only take the supply without waste there would be no objection to give it on the constant system, and the advantages of the constant system would be very great in the houses of the poor. I think that the one disadvantage of the intermittent system is its needing cisterns that are liable to become fouled; and in the houses of the poor it is a most difficult matter to have cisternage so placed as not to acquire some foulness by vitiated air or other contamination. The New River Company have repeatedly offered to furnish the houses of the poor with a constant supply if the landlords of such property would only take water in some way that would insure the company against waste.

Were a constant supply introduced it would be necessary to have very strict supervision indeed, for the purpose of preventing waste, and if that strict supervision could be borne by the inhabitants, and if the requisite power were granted to the companies or to local authorities to control the condition of things in houses, I think that the supply might be brought within more reasonable limits than it reaches to now.

You have been examined upon that point before Mr. Ayrton's committee, have you not?—I have.

Do you advocate the entire abolition of cisterns in the case of a constant supply?—Not at all. I think it would be a very inadvisable thing. I believe the whole question was gone into in the years 1851 and 1852 before Parliament, and the result come to then was that cisterns should in all cases be provided, and it is so arranged in the Metropolis Water Act of 1852. I think in all houses of a better description, where there is a possibility of putting cisterns in proper places, cisterns should still be required, and only in the houses of the very poor should cisterns be dispensed with, and water taken on the constant system through some waste-preventing apparatus.

Although you would retain the cisterns, you would still have a constant pressure upon your mains?—There would still be a constant pressure upon the mains, and a constant pressure upon all mains would be decidedly an advantage, especially for fire purposes. When I speak of mains under a constant system I mean all the companies' pipes, because at present a portion only of the companies' pipes are always charged, and they alone are called "mains" by the companies. Other portions (the branch pipes of the companies) are intermittently charged, and they are called "services." The effect of giving a constant supply to all those pipes would be to enable a direct fire supply by a hydrant to be taken from the "services" as well as from the "mains." But I still say that the difficulty arising out of the enormous expense which would be thrown upon the owners of house property in making houses fit to receive a constant supply would be so great in London, that a general adoption of the constant system here appears to be almost impracticable.

Of what could that expense chiefly consist?—It would chiefly consist in laying down new lead pipes for those at present in use. Many of the lead pipes in London are very old and very feeble, and the least increase of pressure would cause them to give way. The fittings are also of a very imperfect kind. Under the intermittent system those pipes are all saved from the night pressure. The pressure of water at night, when no one is drawing from the mains, is very much greater than the pressure during the day, and as houses are now served, those lead pipes are only subjected to pressure during the day and are saved therefore from the higher

pressure of the night. Under the constant system they would come under that higher pressure, and in the great majority of cases they would give way.

If your view is correct that you could reduce the consumption per head from 30 gallons to 20, there would be a saving in that case of water to the water companies of 33 per cent. ?—There would.

Would not that saving of 33 per cent. in the quantity of water that they supply enable the water companies to bear such an expense as would be involved in the alteration of the services to the houses ?—I think not.

Would the system of constant supply entail a large expense upon the water companies ?—To a certain extent. The New River Company has already incurred a very large expenditure in preparations for the constant supply. It was arranged by the Metropolis Water Act of 1852, that the companies should prepare themselves after an interval to give a constant supply, and that if four-fifths of the inhabitants on any district main should come to a company asking for a constant supply, and put themselves in order to receive it, the company should be bound to give it. Under those Acts of 1852, 1854, and 1857, which I mentioned, the New River Company laid out something like 800,000*l.* in the general improvement of their supply, providing filtering beds, laying down large new leading mains, and constructing high service covered reservoirs, all of which were in preparation for this improved constant supply. As yet no applications have been made for a constant supply, and a constant supply therefore has not as a general rule been given, though there are exceptional cases in the New River district where the supply is constantly on.

What do you understand by the householder putting himself in a position to receive the constant supply ?—The lead pipes must be made of sufficient strength by him, that is, for his own sake. He must take the water for the watercloset use out of a service cistern with a double valve, so that there shall not be waste in the watercloset (one valve always being shut while the other is open). While the water is being drawn into the closet the water is prevented from coming from the main into the cistern, and so waste is effectually prevented. He would require to have all his ball-cocks and taps of the best description, and one thing which has been found almost always necessary in every house in which a constant supply has been given is to forbid overflow of waste-pipes from cisterns, so that consumers shall have a very good reason for taking care that ball-cocks are always in perfect working order.

What do you calculate the average to be per house for making those necessary alterations ?—I have calculated that on the average, to do the thing properly, it would take something like 8*l.* per house all over London in order to put the houses in proper condition for receiving the constant supply.

That 8*l.* would lie between two extremes; what would it be for a small house, and what for a large one ?—I think for a small house it might take 4*l.* or 5*l.*, and in larger houses a very great deal more.

Would you say 12*l.* or 14*l.* ?—Yes. Where the pipes are built into the walls and have to be cut out and the decorations made good, the expense might be 20*l.* and upwards. In some cases it has been said and often felt, I believe, that the companies obstinately stand in the way of a constant supply. I do not think that at all to be the fact. If a constant supply could only be carried out here in London as it is said to have been carried out in some other places, with a great reduction in the quantity of water consumed, the companies should hail it; it would be a great matter to them to be able to dispense with the services of many turncocks, and save water at the same time.

Mr. Greaves says:—

I myself am rather an advocate for a constant supply on the whole. Of course claiming to have the privilege of putting a reduced orifice somewhere on the pipe so as to prevent inordinate waste, I find no difficulty in giving a constant supply in my district. I have now 25,000 houses out of 92,000 who are continuously from year's end to year's end on the constant supply system. 5156–66

Will you explain what you mean by a reduced orifice ?—Somewhere in the pipe between the pipe which belongs to the company and the cistern which belongs to the consumer, a disc with a small hole in it is inserted so as to prevent the water being drawn beyond a certain speed. That limits the draught of the system, and it saves us from inordinate loss which we know we should suffer, because notwithstanding that we have 25,000 tenants supplied in this way we cannot leave them unguarded, we are obliged to visit and inspect continuously over and over again.

That limits the size of the supply pipe to the cistern ?—Yes.

What class of houses do you supply in this way ?—We supply without distinction now.

But does that include any of the poorer class of houses ?—Yes; in fact seven-eighths, perhaps nine-tenths, of all the houses that we are laying on now we are laying on upon the constant system.

And all upon that principle ?—Yes, all upon that principle.

With regard to the poor people your experience would be, I presume, that it is of vital consequence to them to have a good supply of water ?—Yes, it is. I advocate giving a complete and good supply to the poor on every possible ground, moral, social, and physical, with reference to the ordinary comforts of life. I think the absence of a proper supply of water to the poor is one of the grievances of the day.

When you do adopt that system and apply a contracted disc for the water to pass through you have of course to assume that you will allow them to have a certain supply in 24 hours ?—Yes, certainly.

What do you assume in that case ?—I assume, say 180 gallons in 24 hours per house, that is the maximum, that is to say, if they have no ball-cock nor any check upon it and they were to rob me to the utmost they could only take to the extent of 180 gallons a day. A pint a minute is 180 gallons a day.

Have you found that the constant supply to the poorer class of houses has led to any greater waste of water than under the intermittent supply ?—I do not think it has.

He also describes some contrivances introduced by him to prevent waste. 5202–5.

Mr. Beardmore considers that under any system cisterns must be used. He says:— 3347 *et s*

I do not see any possibility of dealing with the general humanity, as you may say, without them. If you have such waste as you have in the low districts in London no pipes can furnish water constantly and with high pressure. You cannot deal with it. If you have a fraudulent or a careless man in one house he is wasting water away, and of course he is diminishing the head to the person next door, that is the difficulty you have got—to protect everybody and to give an equal pressure. At this moment I have the general advising and management of a small board of health town near London, and we profess to give a constant service, but it is perpetually breaking down; one wrongdoer opens a cock, and there is the whole thing at an end, and we have perpetual difficulties, and now I am dividing the services. At Enfield, I have reduced the pressure from 170 feet for the low district to about 35, and the landlords of the houses have already thanked us for doing it. The expense of keeping up the fittings was so great that they liked the low pressure better.

He instances the rigid supervision necessary in towns where constant supply is given, and thinks it would be impracticable in London.

Being asked whether the health of the inhabitants would be promoted by the constant supply system, he says:—

I cannot say that, because I think the real evil is the iniquitous state of the poorer class of houses. They have no sort of cistern at all, and if you made it absolutely requisite to have a very moderate amount of cistern, and proper arrangements for taking in the water, and could keep the people from stealing the apparatus, you will be as well supplied by the present system as by the constant system. At present, in the low parts of London, in the east of London, you cannot keep a tap on a pipe at all; everything goes.

He adds further remarks on the subject.

5587–686. Mr. McClean has adopted the constant service system extensively in waterworks in Staffordshire, and believes it is the proper system. He has found no difficulties in applying it.

3813–18. Dr. Letheby says:—

As an abstract question, there can be no doubt that the constant supply is a very advantageous thing to the public, chiefly because they would get their water cooler, more grateful, less liable to the pollution to which it is now subject after it is delivered by the water companies, and, if the question really turned upon poor people's houses, I should say that the constant supply to them, whether it be in a court by a standpipe, or whether it be in their own yards by a standpipe, would be a boon, the good of which is hardly to be calculated.

2720–25. Dr. Lyon Playfair expresses his opinion of the advantage of constant supply, which he says

Delivers the water always cool and in good condition; it obviates the necessity for a number of cisterns in badly ventilated houses, and especially in the houses of the working classes, and so prevents a great source of the danger of epidemics which arise from the solution of the polluted atmosphere in the water.

3162–8. Dr. Parkes prefers the system of constant supply as doing away with the evils of house storage. He says,—

"There are great sanitary advantages in a constant supply, namely, in doing away entirely with the house storage. The house storage entails a great chance of the water being impure, either from the cisterns being allowed to get filthy or from substances finding their way in from the overflow pipes communicating with sewers and drains, and gases forcing their way back through imperfect traps. All these evils the constant supply entirely does away with, but the disadvantages of the constant supply are certainly the very great quantity of water that is wasted, and the occasional failure at times when it is very important indeed to have a large supply of water. For example, last year, in Southampton, in the time of the cholera, when it was extremely important to have the drains well flushed, and everything carried out, we had rather a failure in the supply of water in the low parts of the town. The population in the higher part of the town being nearer the reservoir used a very large quantity of water owing to the dryness of the season, also their gardens required a large quantity of water, and this was taken from their constant supply. At the same time there happened to be also some alterations going on in the pipes and in the machinery, which also lessened the quantity. The consequence was that we were unable in the low parts of the town for several days during the prevalence of the cholera to ensure a proper quantity of water passing through to the sewers."

"Assuming that you have an ample supply for the whole population of a town, are you of opinion that the system of constant supply for all sanitary purposes is infinitely superior to that of an intermittent supply?—Quite so, if you can get over the practical difficulties and the enormous waste, but I think that if you have the constant supply it must be understood that there is to be no stint in the water in any part of the district at any time as there appears to be in some towns which are supplied with the constant service."

2771 *et seq.* Dr. Simon considers the system of intermittent supply to be a very bad one, for reasons he gives at considerable length.

"Do you consider the system of intermittent water supply to be a good or bad one?—A very bad one.

"What is the reason which induces you to consider it a bad one?—My opinions about it are substantially those which I expressed in 1849 and 1850, in the following passages of my reports then made. From report of 1849:—'I consider the system of intermittent water supply to be radically bad, not only because it is a system of stint in what ought to be lavishly bestowed, but also because of the necessity which it creates that large and extensive receptacles should be provided, and because of the liability to contamination incurred by water which has to be retained often during a considerable period. In inspecting the courts and alleys of the city, one constantly sees butts for the reception of water, either public or in open yards of the houses, or sometimes in their cellars, and these butts, dirty, mouldering, and coverless, receiving soot and all other impurities from the air, absorbing stench from the adjacent cesspool, inviting filth from insects, vermin, sparrows, cats, and children, their contents often augmented through a rainwater pipe by the washings of the roof, and every hour becoming fustier and more offensive. Nothing can be less like what water should be than the fluid obtained under such circumstances, and one hardly knows whether this arrangement can be considered preferable to the precarious chance of scuffling or dawdling at a standcock. It may be doubted, too, whether even in a far better class of houses the tenants' water supply can be pronounced good. The cisternage is better, and all arrangements connected with it are generally such as to protect it from the grosser impurities which defile the waterbutts of the poor, but the long retention of water in leaden cisterns impairs its fitness for drinking and the quantity which any modern cistern will contain is very generally insufficient for the legitimate requirements of the house during the intervals of supply. Everyone who is personally familiar with the working of this system of intermittent supply can testify to its inconvenience, and though its evils press with immeasurably greater severity on the poor than on the rich, yet the latter are by no means without experience on the subject.'"

He goes on to explain the large waste which takes place on the intermittent system, and which, he conceives, reduces the average available supply for domestic purposes within the city to only a quarter of its alleged quantity.

Mr. Holmes, the borough surveyor of Sheffield, says he does not see any advantage in substituting the constant for the intermittent supply except in case of fire; there must be a great waste in the former, going on by night as well as by day. He adds, however, that with pipes capable of withstanding the pressure, he would prefer a constant supply. 4884.

Mr. Dale is arranging a constant supply to Hull. He has found no inconvenience; on the contrary, the leakage is less when the constant supply is given. The inhabitants prefer the constant supply. He says in reply to the question— 1107-19.

"Have you experienced any inconvenience arising from the constant supply?—None at all; far from it; there is far less leakage I should say, and I have tested it in fact. I should say that on the eastern portion of the town there is a saving of 25 per cent., or say 20 per cent. to be on the safe side, in the leakage, compared to what there is on the other side of the town."

He explains how he tested the quantities supplied to each side of the town, and further adds—

"Have you had any complaint from the inhabitants with regard to the change of system?—The inhabitants are continually crying out for a constant supply, they prefer it to intermittent."

Mr. Quick gives evidence as follows in regard to constant service:—

"I think that in the poorer districts it might be an advantage, but I think that practically the better class houses have the best constant supply that they can have by having a good cistern in their houses, by means of which, in the event of any interruption from the breaking of a main, or a conflagration in the neighbourhood, or anything of that kind, they have a supply of water which will last them two or three days in there own cisterns; whereas if they merely depended upon a pipe passing into the house, the moment that there was any interruption to the flow in the main they would be deprived of that accommodation. 6014–92.

Then are we to infer that you are not in favour of the constant supply system?—I think that it has its evils. Perhaps in a poorer neighbourhood it might be an advantage, but I think where cisterns are properly taken care of and cleansed, and so on, that is the best constant supply that anyone can have. In fact, I do not know how the constant supply system is to be arranged in a house, where the kitchen boilers, for instance, require constant filling; and with regard to waterclosets, again, it would be an exceedingly inconvenient thing to have water absent from the house probably for 24 hours in the case of an accident to a main, or anything of that kind.

Are the accidents to the mains of which you speak frequent?—The large valves want repairing occasionally, and the mains will break now and then, and alterations are necessary, such as putting on new branches to a main, and when the main has to be cut out and a connexion made to it to go down a side street during the whole of that time, which may occupy several hours, if there were no storage the people would be deprived of water.

Mr. Quick gives a statement of 4,300 different works done in the Southwark and Vauxhall Company's district during the year 1866, in each of which cases it was found necessary to keep the stopcock on the main or service pipe shut for periods varying from one to twenty-four hours.

Being asked whether the expense of keeping the pipes and fittings in repair would prevent the system being carried out, he says—

We find great difficulty in getting the owners of small property to lay out a single sixpence for benefiting their tenants in any way, and I am quite sure that any representation that the companies could make would never induce them to do it unless there were some legislative power to compel them.

Has your attention been directed to the principle of a constant supply in regard to its effect upon the public health?—I think, as I have stated before, that in the poorer districts there would be a great advantage from the constant supply, but in the better class of property I cannot conceive that there would be any advantage at all in respect of health.

A constant supply would have its advantages for the purposes of fire, would it not?—I think there is a great question whether it would or not.

I mean under proper pressure?—That is the difficulty. If there are so many thousands of taps in connexion with the mains, there will be always a certain amount of draught passing into the district which will lower the pressure. At the present time the whole of the trunk mains or principal mains of the district are kept under the full pressure all night, and in case of fire they have only to open one of the side cocks and direct the water to the particular place where the fire may be burning, and all the pressure can be directed by merely opening these one or two cocks, whichever it may be.

But I wish you to direct your attention not to such a pressure as that the fires might be extinguished from the hydrants by application of the hose, but to such a pressure as would keep the pipes charged and the supply sufficiently full to be pumped by means of a separate fire engine.—That can always done by the mere opening of one of the side cocks leading from the trunk main.

The difficulty now is to find water, is it not, in case of a fire?—The water is always in the main.

A recent case occurred where water was not to be obtained in any quantity for useful purposes for more than 20 minutes after the fire, and the destruction was pretty well completed, how do you account for that?—I think that that arises principally from a want of understanding between the brigade and the water companies.

Being asked what it would cost to put the fittings into proper order to receive the constant supply, as required by the Act of 1852, he says:

It depends upon the class of house, in some cases it might cost 2*l.* or 3*l.*, and in others 10*l.* or 15*l.* per house.

In the present system of supply is it not one of the great objections to the cistern system that those cisterns are not kept clean by the owners of the houses themselves?—That is so.

And if they got the water direct from the pipes, they would get it, would they not, in a purer condition?—There is no doubt of that.

Your view perhaps would be that it would be a necessary thing to have a combination of cisterns and a supply direct from the pipes in the same house?—Yes.

Up to the present time the practical effect of the clauses in that Act of Parliament has been, has it not, that no company has been called upon by the inhabitants to give them a constant supply?—That is so.

Do you think that the water companies themselves would object to it if they were called upon by the inhabitants, and if the inhabitants were to do their part of the duty?—I do not think they would. Of course the water companies would have to lay out a very large sum of money to enable them to do it, and I had perhaps better explain why that would be so. It is on account of the undulations in the districts. In the Grand Junction district there is some portion of it but little above the level of the Thames, whereas other portions are nearly 200 feet above the level of the Thames, and it is constantly rising and falling; and of course if the water is allowed to run to waste in any way in the lower portions of the district, unless there is a division of the trunk mains the high portions would never get any water at all.

Still there would not be an objection on the part of the companies to that outlay?—I think not, if proper provisions were made.

And it would necessarily be attended with much greater stringency of supervision on the part of the water companies?—Yes.

Do not you think that the result would be great economy in the consumption of water per head?—There might be an economy in the quantity of water pumped, but the difference of cost to the companies would not be any very great deal. You would not reduce the expense of management, or labour, or anything of that kind; it would be the mere expense of pumping.

Still there would be economy in the actual consumption per head?—Yes; there is no doubt there would be less water used, supposing that all the fittings were put in a proper state to prevent waste.

Mr. Morris's evidence is as follows:—

6155–60. But you think that a constant supply would be a very good thing?—I do, if we could once prevent waste, or if we had power given to us to prevent it, or any mode were devised by which we could get rid of the enormous waste which is attendant upon a constant supply as carried out under the present system, we have no objection.

When you say if you could get power given you to do so, have you ever considered what powers would be satisfactory for preventing waste?—I think that the power which would be required must be vested in what we may call a water police; there should be a constant inspection, which I know that the public would not bear, but unless we had power to exert that, it is perfectly out of the question. I have made some experiments, and I know that people have wasted as much as 2,000 gallons a day per house for a twelvemonth together.

Having regard to a properly arranged system of supply, pipes of sufficient strength to resist the pressure, and an efficient supervision, you are of opinion in the first place that a constant supply would produce a great saving of water, and in the second place promote the health of the inhabitants?—I will confine myself to the saving of water. I have no doubt there would be a great saving of water, but the restrictions must be very stringent, otherwise it would completely absorb the whole of our power of supplying; you might pour water upon the sea beach with as little effect.

You think it necessary, if I understand you aright, to have some very stringent police regulations?—I do not say police, but something of that nature, persons armed with authority who could go into the houses and prevent waste.

6269. Dr. Frankland says:—

"With regard to the deterioration of the water by storage in cisterns and in tanks, I think that too strong an opinion can scarcely be expressed. In my own house, when I first went to it, I found that the waste pipe from the cistern which was to supply us with water was not furnished with a trap at all, but that there was free communication between the sewer and the interior of my house through this pipe, and sewer gases were brought just upon the surface of the water in the cistern, and I believe that is the condition of most of the houses around me at Haverstock Hill."

6589–6604. Mr. Bateman has given us a paper he wrote on this subject a short time ago, and which, as it is well worthy of attention, we have reprinted in Appendix I. He advocates the constant service system, but it will be seen that he is by no means insensible to the great difficulties that would be met with in making the change in London. He adds, in his evidence, remarks as follows:—

"I may state that my own opinion is that a constant water supply under high pressure in the existing state of the plumbing in London would be almost impossible, and that it is necessary that very stringent powers be given to the companies or to a corporation, if it had the administration of the water, to compel all the parties to put their water fittings into perfect order before the constant supply was given. Even the Welsh district would be almost insufficient to supply London under the constant system, as the fittings are now; but if proper care be taken that the fittings be all properly put in order, and a very strict supervision exercised, I find as a matter of experience that towns supplied under the constant system do not take more water than those which are supplied under the intermittent system. The consumption of water in Glasgow is 50 gallons per head per diem, where water fittings are as bad as they can be, as bad as they are in London (and that is about saying the worst thing for them), and the waste is very great indeed; I forewarned them against this, and for a time very active supervision reduced the waste after the introduction of the Loch Katrine water; but they consider that they have an inexhaustible supply and that it tends to sweeten the Clyde and flush out the sewers, and they allow the waste to go on, but all that might be corrected."

He further adds particulars as to the advantage of constant supply in cases of fire, as illustrated in Manchester. He says:—

'The per-centage of property destroyed from 1846 to 1850, before the introduction of the water, was 21·3 per cent. of the value of property attacked by fire. The amount saved out of such property was 78·6 per cent. From 1851 to 1855, Manchester, for half the time at least, not having advantage of high pressure, and for the latter two years of the time having it, and therefore it would be partly under the old system and partly under the new, the per-centage of property destroyed was 12·9 per cent., and of that saved 87 per cent. Then came the advantage of the constant supply and high pressure, with a full water supply, and from 1856 to 1860 the per-centage destroyed was only 7·7 per cent., being only one-third the amount which was destroyed

before the introduction of the fresh water supply, and the amount saved was 92·2 per cent. From 1861 to 1865 the amount of property destroyed was 6·7 per cent., and the amount saved was 93·2 per cent."

He believes that the expense of alterations in the houses, to receive the constant service, has been much overrated as regards the better class of dwellings.

Mr. Rendle, a medical gentleman who has been very active in promoting sanitary improvements in Southwark, gives examples of the defects in the London supply, for which he believes constant service is the only remedy. 6749 *et seq.*

Mr. Heron, town clerk of Manchester, states that no difficulties of importance have been found in introducing the constant service into that city, and that in the small houses cisterns are dispensed with. There are, however, no waterclosets in the small houses. The arrangements for extinguishing fires are very complete and efficient. Cisterns are useful in cases of stoppage of the supply in the main, though such accidents seldom occur. 7330–41. 7349–53. 7367–70.

His impression is in favour of the economy of the constant supply, but the regulations to prevent waste must be very stringent. He says:— 7386–90.

"We have most ample powers with reference to fittings, and also for the purpose of inspection.

"7388. Would not a similar power be a matter of absolute necessity in the case of London being put upon the constant supply system?—I should think it absolutely necessary in any case. I think it is quite right that whoever is supplying water, whether it is a corporation or a company, should have ample power to see that the water is not being improperly wasted.

"7389. Do you find any complaints from owners of property of such supervision being at all inquisitorial?—Not at all; I never heard a complaint of the kind, and we have found it to be most necessary."

He gives, in answer to question 7390, a list of the regulations provided by Acts of Parliament for this purpose.

Remarks by the Commission.

241. We are of opinion that the mode of distribution is a most important point, particularly as bearing on the health and comfort of the poorer classes; and we agree with the conclusions arrived at on previous public inquiries, that earnest and prompt efforts ought to be made to introduce the constant service system to the farthest extent possible, in the supply of the metropolis.

242. The provisions of the Act of 1852 in this respect appear to have been ineffectual, and we are not unimpressed with the difficulties of the case, which we fear would be beyond the power of being successfully dealt with by the present companies. The legal powers they now possess would not be sufficient to enable them to control the house arrangements, or to check the enormous waste that would arise on the introduction of the new system. And we do not see our way to recommending that they should be invested with new powers which, if they are to be effectual, must be of too inquisitorial a character to allow of their exercise in private hands.

We cannot adopt the suggestions of the House of Commons' Committee of 1867 as to how the details of the arrangements should be carried out, believing that such technical details can only properly be dealt with by competent professional skill, and that they must be carefully determined under the guidance of the experience gained in the process of change. The same Committee recommend, among other things, that the companies should combine with a metropolitan public body to frame rules for controlling the house arrangements, any violation of such rules being penal; but we believe it would be difficult for any such complex arrangement to be made to work satisfactorily.

243. After mature consideration of this important question, we have come to the conclusion that the constant service system cannot be effectually carried out in London so long as the supply remains in the hands of private companies, and we have explained, in Section IV. of this part of our Report, in what manner we conceive the change may be effected.

In any case, however, such a change must be introduced very gradually, and with the greatest precautions, particularly in the poorer and lower districts; and even with all possible care preparations must be made for meeting considerable loss of water in the earlier periods of the alteration.

Compulsory Supply to the Poor.

244. Connected intimately with this subject is that of furnishing a compulsory supply to the poorer districts.

It has been established by law that the supply of water, being a necessary of life, must not be left optional; for though every arrangement may be made for affording a

proper supply wherever it is demanded, experience has shown that it is necessary in many cases to enforce its reception.

We have reason to believe that the companies honestly do their best to supply the poor, and are inclined to be liberal in their arrangements for this purpose; but they complain of the great difficulties they have to encounter.

The Committee of 1867, after reciting the legislative provisions applicable to this purpose, say:—

"These various provisions of the law would seem to be ample for the purpose of ensuring a due supply of water for all purposes for the inhabitants of the metropolis in every house, but your Committee regret to state that they have hitherto failed to effect this desirable object, more especially in the cases where a proper supply of water is most essential."

They recommend an improved system of inspection, under the auspices of a metropolitan public body, and certain alterations in the manner of levying the rates; but we are of opinion that in this case also, the same complete change is called for as in the case of the constant supply.

Section IV.

GENERAL CONTROL OF THE WATER SUPPLY.

245. In a matter of such vital importance to the health of a large population, we consider that it becomes a serious question in what hands the control of the water supply should be placed.

246. The duty of supplying the inhabitants of a city with water has from a very early period been regarded as a peculiarly municipal function; and the supercession of the municipalities by joint-stock companies is a comparatively modern innovation, assuming the New River Company to be the earliest case in point.

Since this case the private companies have very generally exercised the functions in question; but of late years many towns in England have come to the conclusion that the new practice was a fundamental error, and have resumed the ancient principle by taking the control of the water supply again into their own hands. Manchester, Glasgow, Liverpool, Dublin, Bolton, Bradford, Halifax, Leeds, Rochdale, Preston, and many other towns, are instances where this has been done.

247. We have had Mr. Heron, the town clerk of Manchester, before us, and he has given evidence as to the circumstances under which the water supply was taken into the hands of the corporation. The following are extracts:—

7270. "In 1845 the attention of the corporation was more especially directed to this subject; we were in a most lamentable condition, and it was quite clear that some complete change was necessary. Perhaps I may be allowed to state that about that time the second report of the Health of Towns Commission was published—a commission over which the Duke of Buccleuch presided—and which I have no doubt is familiar to this Commission, for in that report it seems to me the subject is almost exhausted; we found it stated that 'the importance of an ample supply of good water, accessible at a price within the reach of the poorer classes of society, and in far greater quantities than have hitherto been furnished, is a subject worthy of the greatest attention.'"

7276. The report states: "It appears to be generally admitted by witnesses examined before us, who, being "themselves connected with existing water companies, have had every opportunity of observing the effect "of the opposing interests of the companies and their customers, that a copious supply of pure water cannot "be secured to the poorer classes of the community, unless the duty of providing it is placed under the "management of some independent body. It should be the duty of the local administrative body not only "to secure a sufficient supply for all the inhabitants, but, by contracting with or purchasing it of the water "companies, to ensure its regular distribution at a fair remunerating price." Another recommendation was—"With a view of ensuring a sufficient supply and proper distribution of water to all classes, we "recommend that it be rendered imperative on the local administrative body charged with the manage- "ment of the sewerage and drainage to procure a supply of water in sufficient quantities not only for the "domestic wants of the inhabitants, but also for cleansing the streets, scouring the sewers and drains, and "the extinction of fire. For this purpose we recommend that the said body have power to contract with "companies, or other parties, or make other necessary arrangements." A further recommendation was—"We "recommend that as soon as pipes are laid down, and a supply of water can be afforded to the inhabi- "tants, all dwelling houses capable of benefiting by such supply be rated in the same way as for sewerage "and other local purposes, and the owners of small tenements to be made liable to pay the rates for water, "as we already recommended in respect to drainage.' The corporation at that time felt so satisfied that it was desirable to carry out those recommendations within the city of Manchester, that we determined to go to Parliament to take power to purchase the works of the existing company, and to go for a large scheme which we believed would be sufficient for our present and prospective wants. But we determined also to go beyond those recommendations, because we determined, believing that it was only right and just, to introduce the principle of a public rate, and I believe it was the first time that the application was ever made to Parliament to obtain power to levy, in addition to a compulsory domestic water rate, a compulsory

public rate, payable in respect of all property of every description within the city. We applied to Parliament in 1845, and then and by subsequent Acts obtained power to carry out a scheme which is not yet, I am sorry to say, completed. In 1848 we went for a second Act, which was simply to enlarge the scheme which was proposed by the Act of 1847 and since then we have had to go for other Acts of Parliament to obtain additional power, both with regard to the scheme itself, and also for carrying out in detail works within the city and the adjoining districts which we supply."

Mr. Heron remarks that one result of this has been that the corporation have been enabled to carry out a plan of water supply of such magnitude as could not have been accomplished by any private company. He says :—

"I feel perfectly satisfied that we should never have had such a scheme carried out unless we had undertaken to do it ourselves. Besides, the expenditure which we undertook was such an expenditure that it is quite certain no private company would ever have dreamt of encountering; nor was it one which they would have been justified in undertaking. A private company could not have acquired the money. If it had asked Parliament they would not have granted them the powers that we obtained; and it is only by the exercise of those powers that we have been enabled to incur such an expenditure, and to supply, as I think I can show you we do supply, water at a very low price to the inhabitants of the city." 7314.

He then goes on to speak of the advantages to the town:

"You are of opinion, are you not, that the supply of water and of gas to any large town should be in the hands of the municipal authorities?—I think the experience that we have had in Manchester has shown to us most clearly that the advantages are very great indeed of the supply being in the hands of the corporation. 7316–8.

"Are you now supplying water, not only more abundantly, but of a much purer quality, to the inhabitants of Manchester at a less cost than that at which they obtained their supply prior to 1845?—At a very much less cost, and we are giving them an unlimited supply of, as we have always thought, as pure water as is obtainable.

"Does that reduction in cost arise from your mode of spreading the burden of supply over all the rateable property as compared with the charge made by a private water company on domestic dwellings only?—In the first place the public rate goes necessarily in reduction of the charge that is to be made for the domestic supply within the city. That is the first important item, and which is obtained by the power which we possess to rate all property within the city. In the second place, no doubt as the question suggests, we can rate all dwelling houses, whether they take the water or not, (but they do take it, every house within the city takes it,) and this power diminishes considerably the amount which would otherwise have to be charged if you were only supplying, say, half or two-thirds or three-fourths of the houses; the cost is the same, the water is there, the water has been obtained, and it costs no more to supply the whole, assuming that we have got the water, which is the fact, than it would to supply three-fourths or one-half of the dwelling houses.

"I gather from your own experience in the case of Manchester that you are thoroughly convinced of the advisability of all corporations undertaking the water supply themselves?—I am perfectly convinced of it. I think the reasons are unanswerable, and one of the strongest reasons is, first of all, that they may obtain power to rate the inhabitants, which I do not suppose would be granted to any private company; they get power to rate everybody whether they take water or not, so as to spread the expense over the largest possible area, and they get that which after all is one of the objects of greatest importance, and I think so reasonable and so just—they get power to tax the whole of the property within the area with a public rate, which is in reduction of the expense of distributing water amongst the domestic consumers." 7355.

The corporation are stated to have the power of levying two rates, one a public or general rate on all property, which is fixed at 3*d.* in the pound, and secondly, a special or domestic rate upon all dwelling houses, which is 9*d.* in the pound, making in this second class of property 1*s.* in the pound on the rateable value, or about $10\frac{1}{2}d.$ on the gross rental. For the 3*d.* rate no water is specially supplied, but the rate is a contribution for the advantages secured to the whole community by their protection in case of fire, cleaning streets, flushing sewers, &c. The 9*d.* rate is for water actually supplied for domestic use. Water is further supplied for manufacturing and trade purposes at prices agreed upon with the corporation. 7277–88. 7395.

Mr. Duncan, the acting engineer to the Liverpool Corporation Waterworks, says that his experience is most decidedly in favour of the corporate bodies in large towns having the entire charge of the water supply. He considers the question is so mixed up with the general health of a town that it is almost impossible to separate it from that view of the subject. In all those towns in England where this has been done the tendency has been altogether in the direction of improvement. Corporations are more easily influenced than companies who have dividends to draw from their supply of water. 2429.

Mr. Hawksley, however, the consulting engineer to the same works, is not favourable to corporation management, public bodies being he thinks more under external influences, and less inclined to be liberal in their expenditure. He admits that a large scheme of improvement for such a city as London could not be carried out by divided companies, but he would prefer amalgamation. 2564–6.

Mr. Bateman, as we have noticed in our description of his scheme, relies on the assumption by the public of the water supply as the only possible means of carrying out any great measure of improvement. He suggests that for such a purpose London has only to follow the example of various towns, where of late the waterworks of companies have passed into the hands of corporations; and he instances Manchester and Glasgow as the two most prominent cases of success. App. E.

2838. 7127. Mr. Simon speaks of the great power which water companies hold in regard to the health of the populations supplied by them; and states that he feels very strongly that the public requires more protection than it yet has against their occasional malfeasances. He says:—

"This power of life and death in commercial hands is something for which, till recently, there has been no precedent in the world, and even yet the public seems but slightly awake to its importance."

248. The expediency and advantage of consolidating the water supply under public control are manifest on many grounds.

In the first place such a measure affords, we consider, the only effectual means of carrying out, in the metropolis, the system of constant supply. We have stated, under the last head, that we conceive the difficulties of introducing this system would be too great to be efficiently overcome by private companies; inasmuch as the great powers necessary for the purpose could only be confided to some public body who would be responsible for their proper application. The unity of action, and the extent of command that would be possessed by such a body, would enable the difficulties to be grappled with far more effectually than could be done by divided and private companies; the divisions of districts would disappear, and hence the store reservoirs and mains might be re-arranged with a special view to the new system of distribution; and the inhabitants would be much more likely to fall in with rules and arrangements established by a public body having no independent interests, than with those made by commercial companies.

Secondly, this measure would offer the best mode of ensuring a proper supply of water to the poor, which, as already stated, has been found impracticable under the present system. For a public control would involve compulsory rating, under which all difficulties of a financial nature, which are the only ones really formidable, would necessarily disappear.

Thirdly, we believe that the consolidation of the various present interests would tend largely to economy. The fusion of the districts; the more convenient re-arrangement of the distribution; the abolition of the several and widely dispersed centres of action; the uniformity of management; and many other beneficial effects of the measure, would all result in saving.

Fourthly, the transfer would tend to improve the quality of the supply, not only by checking the tendency to general abuses, but in particular by ensuring more effectual filtration, which is greatly needed, and which it appears difficult to enforce under the present system. We have already remarked on the neglect of the companies to comply with the provisions of the law in this respect, and may here add that this neglect calls either for more stringent control, or for a more effectual change. If the frequent examination and testing of the water, under public management, showed at any time that the filtration was inefficiently carried out, the public, instead of uselessly complaining, as heretofore, would have the remedy in their own hands.

Fifthly, the change of ownership would increase the probability of beneficial results from the measures already enacted, or any further ones to be enacted, for the purification of the Thames. It is possible there may be some difficulty in effectually carrying out these measures; and we believe that a public body having charge of the water supply would be far more likely to stimulate efficient action on this point than individual commercial companies, who have little power to interfere in the matter. And if, at a future time it should be found desirable to undertake any large and comprehensive measure for increasing the quantity of water, whether from the Thames basin or elsewhere, or for further improving its quality, such a measure could only be carried out by combined action, of which the consolidation under public control would be the most advantageous mode.

Sixthly, this measure would much facilitate the provision of water for all public and municipal purposes, and in particular for the important object of extinguishing fires. The documents we have printed in Appendix BL. furnish an appropriate illustration of the urgent necessity of some change in the latter particular.

249. But independently of these advantages, we believe the public management to be far more correct on general principles than the supply by joint-stock organization, which is obviously only applicable to those cases in which a fairly remunerative return may be anticipated for the capital expended. But a sufficiency of water supply is too important a matter to all classes of the community to be made dependent on the profits of an association.

We are hence led to the conclusion that future legislation should restore the ancient practice. The various important considerations above mentioned;—the increase in wealth

and rateability of the great centres of population;—and the facility and advantage with which, in the cases brought to our notice where the requisite powers have been conferred, these powers have been exercised;—all point to such a solution of the problem.

250. Under this system it would be necessary to abolish the voluntary buying and selling arrangement now subsisting between the consumers and the companies, and to adopt the plan of compulsory rating as at Manchester, Glasgow, and elsewhere. Two rates should be enforced; one a special or domestic rate on all dwelling houses, the other a public or general rate upon all rateable property.

Such rates would assess all property much more equitably than the present tax upon consumers. The cost of the supply of water for extinguishing fires, and for general public objects, ought clearly to be borne rateably by all ratepayers; and to assess such burdens solely on the customers of the water companies is a manifest violation of all equitable commercial principles.

PART VI.

ON THE SUPPLY OF PROVINCIAL TOWNS.

251. Your Majesty's commands to us directed that, after reporting on the suitability, for the supply of the metropolis, of the sources of water in the high grounds of England and Wales, we should further report "how the supply from the remaining sources may "be most beneficially distributed among the principal towns."

252. In accordance with these instructions, we began to make inquiries as to the supply of some of the provincial towns, and as to the gathering grounds in various parts of the country generally available for water supply. But we soon found that such an inquiry must be one of great magnitude, involving a large amount of statistical and topographical investigation extending over the whole kingdom. We felt that it would be impossible for us to undertake this without further powers, while its prosecution would delay, probably for some years, the more important and pressing question as to the metropolitan supply. For this reason we resolved to complete our report on the latter subject, and to limit our recommendations on the former one to a few general principles.

To aid in these researches we have had prepared an elaborate map of the catchment basins of the various rivers in England and Wales; we have published this map in Appendix BN., and it will form, we believe, a useful groundwork for future investigations.

277. 253. We have received evidence from Mr. Bateman, as to the supply of Manchester and Glasgow, and he has also given us valuable data as to the supplies of a large number of towns in the Lancashire district, illustrating his remarks by the map, Appendix BO.

2097 et seq. 2570–80. 4620. 1381–407. 277–9. 1061 et seq. 4774 et seq. 4964. 5653–5735. We have also had much evidence about the supply of Liverpool, from Mr. Duncan and several other witnesses.

Mr. Dale has given us some information as to the supply of Hull, and we have already mentioned, in Part I., his proposal for bringing water from the Westmoreland lakes for the supply of various towns in Yorkshire and Lancashire.

Some particulars as to the supply of Sheffield are given by Mr. Holmes, borough surveyor, and Mr. Jackson, chief constable.

Mr. McClean describes the works he has constructed for the supply of various towns grouped together in Staffordshire, and which are illustrated by the map, Appendix BD.

254. We have alluded, in Part I. of this report, to the proposal made by Mr. Bateman, that if his plan for supplying London from the hills of North Wales were carried out, his aqueduct might be used for the supply of a large and very populous manufacturing district in the midland counties through which it would pass. Messrs. Hemans and Hassard also contemplate affording a large supply to towns in the centre of England, by their conduit from the Lake district.

255. There are two remarks of a general nature that suggest themselves in regard to provincial supplies.

In the first place, it appears to us that the Legislature should always jealously watch any proposal for a town taking water from a gathering ground at a distance from it, lest by so doing it may deprive other places nearer to such gathering ground of their more natural source of supply. Mr. Bateman has put this argument so forcibly in the case of Liverpool that we may quote his words:—

277–9. "I think that it was altogether wrong that Liverpool should have been allowed to go to this district, because Darwen, Accrington, Blackburn, Wigan, and many other places are large and flourishing towns closely contiguous to the Liverpool gathering grounds, the whole district having a dense population where the inhabitants can only look to this little cluster of hills for a supply of water. Liverpool has put its paw upon that supply, and has very considerably limited the power of the surrounding districts getting an additional supply of water; and I would venture to suggest, as it is a national question, that if Liverpool should be permitted to go to Bala Lake for water, where it may take water without injury to any manufacturing interest, those hills being as it were the great manufacturers of water, the Rivington district should be held liable to have water abstracted from it for the supply of any neighbouring town which could not otherwise get a supply of water."

This argument ought not to be lost sight of in regard to the proposals for supplying London from Wales or Cumberland; for before either of these plans could be approved, it ought, we think, to be conclusively shown that the abstraction of water from these sources

could not stand in the way of the supply of other places nearer to them. In regard to the Lake scheme, this would be, we conceive, a very powerful objection, as that district has already been several times pointed to as the best source of supply for large and growing masses of population in the north and centre of England.

At any rate, when circumstances render it necessary that water should be brought from a distance, care should be taken to include in the scheme the supply of all places along the route by which the water is conveyed. In the case of Liverpool, for example, if water should be procured from the upper Dee, as is proposed, the project should embrace the supply of Chester and all other places on the way.

256. Then, secondly, we would strongly call attention to the remarkable tendency that towns in the manufacturing districts have to arrange themselves in groups. Take for example the enormous group around Manchester, the group of the Potteries, the group of towns immediately to the north of Birmingham, the groups on the Tyne and near the mouth of the Wear, and many other instances.

This tendency ought always to be considered as an essential element of any arrangements for water supply. Such a group of towns uniting together may go for a much better and more perfect scheme than any one of them separately, and the Legislature ought not only to encourage but as far as possible to compel such a combination.

Instances of the favourable effects of such combinations are afforded by Manchester, which sends, or contemplates sending, supplies in all directions radially around the city, and in Staffordshire, where several towns have been successfully supplied in this way by Mr. McClean.

On the other hand, instances of the unfavourable results of a neglect of this precaution have been experienced in some parts of the country.

Referring again to the Cumberland Lake district, it is obvious that it might be made, by a united effort, available for providing an almost unlimited supply for great groups of manufacturing towns in the north of England ; but it is only by a large union of districts that the expense of such a scheme could be justified.

We therefore consider that when any town belonging to a large group, particularly if forming the nucleus of it, comes to Parliament for a water bill, the scheme should be so designed as to include the whole group.

SUMMARY OF CONCLUSIONS AND RECOMMENDATIONS.

(The figures in the margin refer to the paragraphs, in the body of the Report, from which these conclusions and recommendations are taken.)

257. We may now give a summary of the conclusions we have arrived at on the whole inquiry, and of the recommendations founded thereon.

As to the Plans for obtaining Water from the Mountainous Districts of England and Wales.

§§ 31, 58–64. 258. We are of opinion:—

That Mr. Bateman's scheme is, in an engineering point of view, feasible and practicable, and that by it a large supply of water might be obtained for the metropolis; but that

§ 36. experience warrants great caution in judging of the sufficiency of a gravitation scheme of such magnitude.

That the quality of the water would be satisfactory as regards its purity; but that

§§ 25, 32. there are points dependent on its softness and colour, which might render it less suitable for the supply of the metropolis than the harder water at present used.

That the outlay for the scheme would be very large, amounting, according to the evidence laid before us, to about 11,000,000*l.*; but in the absence of detailed surveys, and in a project involving works of such great magnitude and novelty, and subject to

§§ 33, 34, 35. such large contingencies and elements of uncertainty, we do not consider that it is possible to arrive at any trustworthy estimate of the cost.

That, even assuming the work could be carried out for the estimated amount, the cost to the metropolis of obtaining water by this scheme would be much greater than is

§ 38. incurred by the present plan, and would continue to be so up to any quantity likely to be required within a reasonable lapse of time.

§ 39. That the scheme, if ever brought before Parliament, would probably be strongly opposed by interests connected with the River Severn.

That grave doubts may be entertained whether it is desirable that the metropolis should be dependent on one source of supply so far removed, and which might be liable to accidental interruption.

That great anxiety would be felt as to the formation of immense artificial reservoirs at the head of the Severn Valley.

That as to Messrs. Hemans and Hassard's scheme for supplying the metropolis from the Lake district, the same general remarks apply; the distance is greater, the estimate higher, and the gathering ground more likely to be claimed for nearer supplies.

As to the Quantity of Water available from the Thames Basin.

§ 148. 259. We are of opinion:—

That the River Thames, supplemented, if necessary, by works for storing the flood waters, together with the River Lee, and the water obtainable from the Chalk to the

§§ 82–94. south and south-east of London, as well probably as from the Lower Greensand, will furnish a supply sufficient for any probable increase of the metropolitan population.

That the abundance, permanence, and regularity of supply, so important to a large metropolis, are secured much more efficiently by the great extent and varied geological character of a large hydrographical basin such as that of the Thames, than by the necessarily very much more limited collecting areas that can be made available on the gravitation system. In the former case also the supply streams are self-maintaining, while in the latter the channel must be subject to the accidents incident to its artificial construction.

As to the Quality of the Water from the Thames Basin.

§§ 213–215. 260. We are of opinion:—

That there is no evidence to lead us to believe that the water now supplied by the companies is not generally good and wholesome.

That for drinking purposes the hardness of the Thames water is quite unobjectionable, and in no way prejudicial to health. The weight of evidence seems in favour of hard water, as more free from certain dangers inherent in soft waters on account of their greater solvent power. §§ 165. 174. 213.

That for cooking no important objection to the Thames water has been clearly proved, except as regards the deposit in kitchen boilers, which deposit is easily removed. § 169.

That for washing, and for manufacturing purposes generally, soft water is preferable as more efficient and more economical, but there appears no means of expressing the amount of saving in a money estimate. Looking, however, to the fact that the hardness of the Thames water is moderate in degree, and is still further reduced by boiling, and considering also that the proportion of the whole metropolitan supply used for manufacturing purposes is exceedingly small, we cannot see that this advantage is of sufficient importance to render it necessary to go to a great distance for soft water. § 173.

That the artificial softening process does not appear to be applicable to the Thames waters on a large scale. § 176.

That perfect filtration is highly essential to the good quality of the water supplied; that this process is at present in many cases very imperfectly performed; and that more efficient means of enforcing the provisions of the law in this respect are required. §§ 209–212.

That when efficient measures are adopted for excluding the sewage and other pollutions from the Thames and the Lee, and their tributaries, and for ensuring perfect filtration, water taken from the present sources will be perfectly wholesome, and of suitable quality for the supply of the metropolis. §§ 216, 217.

As to the Quantity of Water likely to be hereafter required for the Supply of the Metropolis.

261. We are of opinion:—

That a probable increase of population to 4,500,000 or 5,000,000 may have to be provided for, though we believe that the time for such an extended provision will be very remote. § 223.

That 200,000,000 gallons per day is the highest demand that need be reasonably looked forward to for the metropolitan supply. § 229.

That the various companies are prepared, with only moderate additions to their present engineering means, to supply a quantity little short of this amount. § 232.

As to the System of Constant Service.

262. We are of opinion:—

That the constant service system ought to be promptly introduced, to the farthest extent possible, in the supply of the metropolis. § 241.

That it cannot be effectually introduced in London so long as the supply remains in the hands of private companies, to whom it would be inexpedient to confide the great powers necessary for the purpose. §§ 242, 243.

As to the general Control of the Water Supply.

263. We are of opinion:—

That it is a matter of vital importance that an abundant supply of water should be provided for all classes of the population, as well as for general public purposes, street watering and cleansing, public fountains, and extinguishing fires. §§ 245–250.

That for these purposes, there should be a power of levying, as at Manchester, Glasgow, and elsewhere, two rates, one a special or domestic rate on all dwelling houses, the other a public or general rate upon all rateable property.

That no trading company could be permitted to levy or expend such compulsory rates, and that therefore the future control of the water supply should be entrusted to a responsible public body, with powers conferred on them for the purchase and extension of existing works, and for levying the rates referred to.

That this plan offers the only feasible means of introducing efficiently the system of constant supply, and for securing a compulsory supply to the poor; we believe that it would tend to economy, to the improvement of the quality of the water, and to ensure the proper provision for public objects and for extinguishing fires; and that it would increase the probability of beneficial results from the purification of the Thames. § 248.

As to the Supply of Provincial Towns.

§ 255. 264. We are of opinion:—

That no town or district should be allowed to appropriate a source of supply which naturally and geographically belongs to a town or district nearer to such source, unless under special circumstances which justify the appropriation.

§ 256. That when any town or district is supplied by a line or conduit from a distance, provision ought to be made for the supply of all places along such line.

That on the introduction of any provincial water bill into Parliament, attention should be drawn to the practicability of making the measure applicable to as extensive a district as possible, and not merely to the particular town.

All which we humbly submit to Your Majesty's gracious consideration.

RICHMOND.

MINUTES OF EVIDENCE

TAKEN BEFORE

THE COMMISSIONERS

APPOINTED TO INQUIRE INTO THE

WATER SUPPLY WHICH CAN BE OBTAINED FOR THE METROPOLIS AND OTHER LARGE TOWNS.

Wednesday, 6th February 1867.

PRESENT :

HIS GRACE THE DUKE OF RICHMOND IN THE CHAIR.

Sir JOHN THWAITES.
Colonel HARNESS.
Alderman Sir BENJAMIN PHILLIPS.
THOMAS ELLIOT HARRISON, Esq.
JOSEPH PRESTWICH, Esq.

JOHN FREDERIC BATEMAN, Esq., examined.

J. F. Bateman, Esq.

6 Feb. 1867.

1. (*Chairman.*) You are, I believe, a civil engineer and a Fellow of the Royal Society ?—I am.

2. And you have for many years given great attention to the question of water supply in various parts of the United Kingdom and elsewhere ?—I have.

3. Will you give us, in the first place, the population of the metropolis in the year 1861 ?—According to the population returns for that year the population within the district of the Metropolitan Board of Works was 2,803,034 persons.

4. What is the present population ?—The present population, taking the rate of increase at which the metropolis in recent years has been increasing, is upwards of 3,000,000 by estimate. Dr. Letheby, in December 1866, gives the population at 3,067,000 in round numbers. The rate of population has been as follows : it has trebled since the beginning of this century, it has doubled itself in the last 40 years, and it is now half as large again as it was 20 years ago ; therefore, at the same rate of increase, in 20 years, it will be half as large again as it is now, and will amount to 4,500,000 persons. I believe that that will scarcely represent the whole population which may be expected to reside in the immediate neighbourhood of London at that time, because the suburbs of London beyond the area included in the district of the Metropolitan Board of Works are so rapidly increasing that they may be taken as forming a part of the metropolis, and ought to be considered with reference to any supply of water.

5. Are you prepared to give us the quantity of water usually set apart for each individual ?—It varies very much, according to the character of the place and the class of inhabitants ; it varies from 15 or 16 gallons a head per day to 50 gallons a head per day, and therefore each town and each city must be taken with reference to its own existing circumstances and what the probabilities are of the supply of water being greater or stationary. Therefore upon that point I think that it would be better to take the actual consumption which exists in London, having reference also to the manner in which it has increased during the last 20 years.

6. Can you give us that information from any official documents ?—I can give it from official documents. In the papers which were prepared by the metropolitan water companies, and which are published in a report of the General Board of Health on the supply of water to the metropolis, which is a public document, and which report was presented to both Houses of Parliament in 1850, the total quantity from the returns of the water companies which was then supplied appears as 44,383,332 gallons per day. In a subsequent report made to the Right Honorable William Cowper in the year 1856 there is this observation : " According to the return furnished " by the several water companies in 1850 it appeared " that 270,581 houses were then supplied with water, " the gross daily quantity delivered having been " 44,383,332 gallons." Those are the figures which I have given you. " It will be observed from the " preceding table that the supply of water to the " metropolis has now reached the enormous quantity " of upwards of 81,000,000 gallons per day, it having " been nearly doubled in the short space of six years." Then I give you a more recent account which is not from an official document, but which has been prepared by the aid of some of the water engineers of the existing companies, and which appears in a pamphlet which your grace I believe has had. There are some tables there which it may be useful to refer to. They are drawn up precisely in the form of the table which appeared in the report to Mr. Cowper in 1856. The estimated quantity of water used, and the amount of outlay, and other figures which vary from the paper submitted to Mr. Cowper, I obtained from the information of Mr. Quick, the engineer of three of the London water-works companies, corrected by personal interview with Mr. Simpson, who is also the engineer of three of the London water companies. I have likewise the opportunity of knowing that, as far as it goes, it is correct with reference to the East London Company, with which company I am professionally connected, they having recently consulted me on their supply of water. According to the information thus obtained, the quantity of water supplied in the year 1865 was 108,000,000 gallons per day. According to Dr. Letheby's returns, which are made to the Registrar-General, and according to a report of Dr. Letheby's in December of last year, the average daily supply for the year 1866 was 92,734,100 gallons. The average daily supply would not nearly represent the actual quantity which on some days would be taken, because not only does the supply increase during the

J. F. Bateman, Esq.

6 Feb. 1867.

year at a very considerable rate, but the irregularity of supply is very great, inasmuch as 15 or 20 per cent. more is required on one day than is required on another day, and, therefore, no doubt the quantity would occasionally considerably exceed the quantity which I have put down. The 92,734,100 gallons was the average daily quantity supplied by the eight London water companies. The Registrar-General's return, from which that return is extracted, which is a public document, gives the quantity for every month. The highest quantity according to that was in September, namely 100,864,971 gallons. For the months of July and August I have unfortunately lost the returns. Probably in July and August, which are the two hottest months in the year, the supply would be greater than that; but you will see very clearly how the supply is increasing. The average supply for the first four months of the year, January, February, March, and April, was 88,285,000 gallons a day, and the average supply for the last four months, September, October, November, and December, was 97,364,000 gallons. Now the quantity of water which may be reasonably supposed to be consumed for all purposes would be as nearly as possible the same during the last four months of the year as during the first four months of the year. There is always less water consumed in the winter months than in the summer months; but if you take four summer months and compare them with four winter months, or four spring months, as you must do if you take the year only, and if you compare the first four months with the last four months of the year it is as fair a comparison as you can make. Therefore you may take the increase at 9,000,000 gallons a day on the average of the last four months, as compared with the average of the first four months, being in the space of eight months rather more than 10 per cent. of increase. If you look at the returns which I have previously given you will find that the increase during the last nine years has been at the rate of 3,000,000 gallons per day.

7. (*Sir B. Phillips.*) Is all that increase from the same sources?—Yes; there has been no alteration of sources within that period, but the annual increase on the average of the last nine years is 3,000,000 gallons.

8. Then is it to be understood that you now get 150,000,000 gallons of water per day?—In 1856 81,000,000 gallons were delivered, and at the present time, whether you take the Registrar-General's return or the estimate which I have prepared from the information supplied by the engineers themselves, the amount is in round numbers rather more than 100,000,000 gallons a day. The 150,000,000 gallons (it is 158,000,000 upon the paper before you) refer to the capability of the existing companies, the water which they have at command.

9. Are we to understand from you that the present absolute supply is 108,000,000 gallons per day?—Thereabouts.

10. And that in 1850 it was 44,383,332 gallons?—Yes.

11. (*Sir J. Thwaites.*) I understood your answer to be that the supply per head differed in different towns?—Yes.

12. Ranging from 15 to 50 gallons per head?—Yes.

13. What in your judgment would be a fair and proper supply, having regard to health and sanitary arrangements?—The present quantity of water supplied to London, divided by the gross population over whom it extends, is 36 gallons per head per day, and I do not think that it would be safe to estimate upon a smaller quantity; indeed, looking at the constantly growing consumption, or waste of water, 40 gallons per head per day for the population of London, including all purposes, would be as little as you ought to calculate for.

14. (*Mr. Prestwich.*) Between 1850 and 1856 it would appear that the increase of supply has exceeded the increase of population?—Yes, but that was an exceptional period. Between 1850 and 1856 very large works were constructed by the existing water companies which enabled them to give a bountiful supply.

15. (*Mr. Harrison.*) Can you give the population in 1850 and in 1856 approximately?—These returns do not give the population, but they give the number of houses supplied; that, however, does not give you the population, because it may not represent the whole. In 1851 you can get the population by the population tables, and in 1856 you can arrive at it by computation; and I do not think that you can get it in any other way. I have not that information at present, but I can prepare it for you.

16. What is the supply per head in Glasgow?—In Glasgow it is 50 gallons per head per day, and in many of the Scotch towns it amounts to upwards of 40 gallons—between 40 and 50 gallons.

17. (*Sir J. Thwaites.*) Does that include the supply for all domestic purposes, including baths?—It includes the supply for all purposes, not only domestic purposes and baths, but trade consumption; and therefore the trade consumption is to be deducted as special trade consumption, which is sold by measure, from the quantity of water which would be supplied to the inhabitants. The net consumption is about 46 or 47 gallons per head per day in Glasgow for domestic purposes and for general sanitary purposes, not including trade purposes. In Manchester the gross quantity of water supplied to about 600,000 persons is about 21 or 22 gallons per head, and of that about one-third, as nearly as can be estimated, is supplied for trade purposes, leaving the actual quantity consumed for domestic wants and general town purposes about 14 or 15 gallons per head.

18. (*Col. Harness.*) Did I understand you rightly that in Glasgow the 46 or 47 gallons per head did not include trade purposes?—That does not include trade purposes; the 50 gallons per head per day does include trade purposes; it includes an enormous amount of waste, and in Glasgow, by due economy and very strict regulations, I have no doubt the consumption can be brought down from 50 to 40 gallons, which would still leave a large quantity. But it is desirable to see the reasons for so large a quantity being used in Glasgow as compared with other places. In Glasgow every house consists of what are called flats; there are scarcely any self-contained houses, and the necessity of waterclosets is absolute, and there being an abundant supply of water from Loch Katrine, the practice has become very general of introducing into houses of as low a rent as 10*l.* or 12*l.* a year, or even lower, a bath as well as a watercloset, so that the quantity of water consumed there is greatly in excess of that consumed in a town like Manchester, where baths are not so generally introduced, and where there is scarcely a watercloset in the houses of the lower classes. The legitimate supply in London ought I think to be as large as the legitimate supply in Glasgow, because you can hardly do without waterclosets; they are almost a necessary appendage to every house in London, and you may have, and probably will have, baths introduced to almost as large an extent in London as in Glasgow. There is no power of restriction, except you make it prohibitory to use water for such purposes.

19. (*Mr. Harrison.*) Taking it generally, do not you find that an increased consumption has been going on gradually in all towns where they have an abundant supply?—Yes; and everywhere where town improvements have extended a watercloset has been substituted for the ordinary privy.

20. (*Sir J. Thwaites.*) Then do you think that in gauging the supply necessary for the metropolis it would be safer to take 40 rather than 36 gallons per head?—Looking to the future I certainly should not estimate it at less than 40 gallons per head.

21. (*Chairman.*) Having paid attention to this subject, you are no doubt prepared to tell us what districts of England or Wales you consider the best from which water can be obtained to supply the metropolis and other large towns?—I think that before you go directly to that point you ought to consider the general

character of the district from which water can be obtained. I think that you ought rather to consider the possibility of getting water from any high lands which might be near to London, and that I presume would include the high lands forming the summit of the drainage ground of the river Thames.

22. Confining yourself to the high districts of the country, will you state from whence in your opinion the best supply of water can be obtained?—According to my opinion (and in that I believe I should coincide with the opinion of most gentlemen who have given attention to the subject) the supply for London, and for every community, ought to be sought for at the purest sources, and where the water is softest, and also where it is most abundant, and where it is most secure from being injured by any operations of agriculture or manufacture, and if those are to be the conditions you must go to the mountains, and you must go to mountains which are not likely to be cultivated; you must, if you can, go to the primitive or the barren formations where little cultivation takes place, and where no population is likely to collect. You must also consider the quantity of water which may be procured, and the possibility, if it is not sufficient in itself at all times in dry seasons, of making reservoirs to store it if there are not natural lakes which will supply the means of storage. The nearest high land to which you can look, from which water can be obtained in a district which will fulfil all these conditions, is North Wales. The rain there, reasoning from like physical conditions, and from actual observations so far as they have extended, is as great as it is in the Highlands of Scotland, and as great as it is in the lake districts of England, with the exception possibly of a particular locality in the lake district which gives an excessive amount of rain from local circumstances which can be easily explained. The extent of ground may be almost said to be inexhaustible from which you can collect water, having reference to the purpose to which you put it, and the elevation at which the water can be collected is such that it can be brought to London at a considerable declivity. I have considered that in laying out any scheme for the supply of London no scheme ought to be entertained at all if you have to go to any distance for the water, and to incur any expense for works of a permanent character which cannot be easily added to or altered afterwards, which would supply you with less than 200,000,000 gallons a day, nor if it were limited to 200,000,000 gallons a day; it ought to be capable of further extension, and looking forward to the future upon so large a question you ought to be able to see your way to obtaining 300,000,000 gallons a day. In the scheme which I have drawn out, and which I prepared as long ago as 1860 and 1862, having thought well over the matter and knowing almost every part of England, and particularly the mountain parts of England and Wales, I prepared a project for bringing in 220,000,000 gallons of water per day, which is double the present supply, and which therefore at the same rate of consumption would be equal to double the present population. That supply might be expected to last for from 35 to 40 years. I selected land in the northern portions of Wales south of Snowdon, south of the very highest part of Wales, lying to the east of Plynlimmon and to the east of Cader Idris, two of the highest mountains. I selected two districts, each capable of affording something more than 100,000,000 gallons of water a day, after giving compensation in water to the streams from which water would have to be collected, but with power of almost indefinite extension existing in the same basin, namely the basin of the Severn, and in the upper part of the river Wye which adjoins. Between the two valleys near Llanidloes there is a low pass by which the head waters of the Wye may be easily diverted into the head waters of the Severn.

23. (*Sir J. Thwaites.*) Can you give us the rainfall of those districts?—The rainfall of the particular district to which I am about to draw your attention has only been taken upon the ground itself since September of last year, but there are many portions of Wales in which the rain returns have been taken for some few years back. There do not appear to have been many meteorologists in Wales, and therefore we are rather short of meteorological information as compared with other parts of the country. In the lake district, Dr. Miller, of Whitehaven, many years ago established, very much with my assistance and that of my friends, rain gauges over a large portion of the lake district, and ascertained the fall there. In Wales, in the year 1865, taking rain gauges which were fixed either within the mountainous district or upon the slopes or tops of the mountains, taking nine different places, as near the ground selected as I could get them, the average rain for 1865, which was almost the driest year in the north of England of which we have any record, was 59 inches. The two districts to which I have referred are those coloured upon this map red and green. The rainfall at Dolgelly, which is just at the foot of the mountains, only at 500 feet above the level of the sea, was 57·59 inches in 1865. There is a place 700 feet above the level of the sea, namely Trawsfynedd, at which the rainfall was 48·18 inches. At Festiniog it was 57·22 inches, that being 600 feet above the level of the sea. At a high point 1,140 feet above the level of the sea, namely Rhiw Brifdir, it was 74·49 inches. At Beddgelert, which is just at the gorge of the mountains, and which is only 330 feet above the level of the sea, the rain was 81¼ inches. At Bettws-y-coed, which is on the east of the Snowdon range, and which is only 70 feet above the level of the sea, the rainfall was 54·13 inches. At Llanberis, which is under Snowdon, and which is 370 feet above the level of the sea, the rainfall was 75½ inches. At Rhayader, which is at the head of the river Wye, getting into rather more open country, and which is 880 feet above the level of the sea, the rainfall was 41½ inches. At Llanidloes, which is 750 feet above the level of the sea, it was 43⅓ inches. The average of all those figures is 59¼ inches. Now, in order to draw conclusions from those facts, as compared with gauges which have been kept in other parts of the country, I have taken nine places as nearly as possible under similar circumstances, but giving the advantage in point of altitude to the mountain gauges which have been kept in the lake district. I have selected these places with a view to make them as fairly comparative as may be. There is one particular locality in the lake district which in one spot last year had as much as 224 inches of rain; that was the Stye, which is close to Seathwaite. That is owing to a particular conformation of country. Wastwater is exposed to the south-west wind, and the hills on each side are the highest hills in the lake district, and the whole of the cloud brought by the westerly breezes is jammed fast in this gorge (*pointing to the map*), and then it goes over the pass at Stye Head, which is about 1,350 feet, and it is then sheltered from the winds and deposits the whole of its contents in the little valley at the head of Borrowdale. At Keswick, at a height of 300 feet, the rain in 1865 was 42·63 inches. At Scawfell Pike, which is 3,200 feet above the level of the sea, it was 49·12 inches. At Derwent Island, which is 250 feet, the rain was 49¼ inches. At Great End, a mountain 2,982 feet high, the rain was 59½ inches. At Brant Rigg, at a height of 695 feet, the rain was 68¼ inches. At Esk Hause, the height being 2,550 feet, it was 61½ inches. At Ambleside, the height being 553 feet, it was 71 inches. At Patterdale Hall, on Ullswater, the height being 450 feet, it was 62 inches. At Wasdale Head, the height being 247 feet, it was 75¾ inches. Those are all situations which, perhaps with one or two exceptions, compared with what I have given you in Wales, are favourable to a large quantity of rain. The average of all those figures is 59·89 inches, as compared with 59·24 inches, which is the average of the gross returns of the gauges in Wales. Now there are certain exceptional places, which I have pointed out, which in 1865 showed the following returns of rain:—Stonethwaite, at a height of 330 feet, was

J. F. Bateman, Esq.

6 Feb. 1867.

84·13 inches; Stye Head Tarn, at a height of 1,472 feet, was 99·85 inches; Sprinkling Tarn, at a height of 1,985 feet, was 103·84 inches; Seathwaite, at a height of 422 feet, was 106·61 inches; and the Stye, at a height of 1,077 feet, was 149 inches; but, so far as we know, there is no locality in Great Britain which gives the same quantity of rain. I believe that in the highlands of Scotland, and in the Welsh hills, particular districts might be selected which would almost give the same return, but the general average of the whole of the remainder of the lake district may be taken in an average year at probably 70 or 80 inches, and in a year of drought, like 1865, at 60 inches.

24. (*Sir B. Phillips.*) What is that as compared with the Welsh district?—The same. I do not believe that there is any difference between the rain falling in North Wales and the rain falling in the lakes.

25. (*Sir J. Thwaites.*) What is the area of the red portion on the map, and of the green portion?—They are each about 66,000 acres.

26. You have so many thousand acres in the red and in the green portions, and you calculate that from that gathering area you will have a given quantity of water. What principle do you adopt?—I am coming to that by and by. I was about to draw attention to the physical character of the two districts. In the lake district of Cumberland we know the actual fall of rain; we only know it in the last three or four years in Wales, under very similar circumstances; but you will observe, that taking the valley of Wastdale and the great valleys which supply the rain, they are gorged in by mountains about 3,000 feet high, and the whole surrounding country is mountainous. The valleys radiate in every direction from Scawfel Pike, the principal ones being open to the south-west. In Wales all the valleys are open to the south-west, and the hills are 3,500 feet high at Snowdon, and nearly 30,00 at Cader Idris, and all the mountains approach 3,000 feet in height. The greatest quantity of rain upon summits which lie between 1,000 feet, and, perhaps, 1,700 or 1,800 feet high, is almost always found on the easterly side of the summit. The rain on the westerly coast is perhaps about 36 inches. It increases at the foot of the mountains, going, say from Liverpool to Hull, to about 40 inches. On the summit of the hills it is from 50 to 60 inches. It is a trifle in excess of that on the eastern foot; further east it is down to 30 inches, and at Hull it is down to 20 inches. I merely draw your attention to these physical features in order to show the conditions which favour a deposition of rain. It may be supposed to be deposited by currents of warm air charged with moisture, impinging against the mountains, and then rising into colder regions, by which means the water is condensed and precipitated and falls in the form of rain, the hills being natural condensers. I will now give the returns of rain since September of last year in the district itself which I propose to lay under contribution for water. These returns are for the three months, October, November, and December 1866, and I may here observe that although one or two of those months in some parts of the country were excessively wet, as in the north of England, and also in the south of England, and in the district of the lakes, yet in Wales there seems to have been scarcely the average amount of rain. In the valley south-west of Llanidloes the rain for the three months was 15 inches. On the hills above Llanidloes it was 24·9 inches. In the valley at Carno it was $12\frac{1}{2}$ inches. On the hills near Can-Office it was $18\frac{1}{2}$ inches. In the valley at Llanwddyn it was $16\frac{1}{2}$ inches. On the hills above Llanwddyn it was 24·8 inches. In Scotland, in the Loch Katrine district, which is a district very similar in altitude and conformation, but not quite so exposed to the west, the rain for those months at Loch Venechar, which is one of the lakes which is put under contribution for the supply of the mills and the streams in the case of the Loch Katrine waterworks, was $17\frac{1}{2}$ inches. For the same three months at Loch Drunkie, which is a little higher up, it was $21\frac{1}{2}$ inches. At the Bridge of Turk, lying at the head of Loch Venechar it was 21·2 inches. On the hills near Glen Finlas it was 16·8 inches. At Glengyle it was 29·2 inches, that being a very wet place indeed. At Loch Dhu it was 27·2 inches. At Aberfoyle it was 20·7 inches. On the hills near Loch Ard it was 23·2 inches. On Ben Lomond it was 30·3 inches. At the Mugdock reservoir, near Glasgow, it was 17·3 inches; and on the hill above the Loch Katrine tunnel it was 27·2 inches. Comparing those figures with the Welsh returns for the same period, taking valley gauges and hill gauges together, we have about $19\frac{8}{10}$ inches in the Welsh district against about $20\frac{1}{10}$ inches in the Scotch district, and therefore the rain in Wales in the last three months of the year 1866 was almost precisely the same as at the Glasgow waterworks. The table before the Commissioners will show the average rain there for many years. The rain at all the places which I have named during that period is shewn in this table, from which may be obtained the average of all the years since 1854 inclusive—$61\frac{1}{2}$ inches, $67\frac{1}{2}$, $59\frac{9}{10}$, $59\frac{8}{10}$, $91\frac{1}{2}$, $82\frac{7}{10}$, 88, $54\frac{2}{10}$, 85, and $90\frac{6}{10}$. The average of those figures cannot be less than about 75 inches—last year it was rather in excess of that—so that we should be justified in taking as the average something like 75 inches of rain for the district in Wales. But as it does not do to lay out waterworks upon an average, we take the two or three driest consecutive years which we can find, and in doing so we should be quite justified in taking 60 inches; that was about the amount of rain in 1865, which was the very driest year during 11 years' returns. Having determined the amount of rain which we may reasonably expect, we then come to the quantity of that rain which is available for useful purposes. We must take the portion which is available to supply the rivers or towns; and from a great number of observations, to which our experience is constantly adding, we know that according to the declivity and the geological character of the country, and the cultivation and the amount of vegetation, the quantity which is taken up by vegetation, or is evaporated or lost to the rivers, varies from about 9 inches to 16 inches, the smaller quantity being of course that where the rocks are the hardest, and the declivities are the greatest, so that the water comes down in floods. If we take 12 inches as the mean between those extremes it will leave us 48 inches as the net available produce of these districts.

27. (*Chairman.*) Then are we to understand that the net available produce from the Loch Katrine district, whence you supply Glasgow, is 48 inches?—The net available produce of the Loch Katrine district is quite 48 inches.

28. (*Sir J. Thwaites.*) Do you gather that from the discharge?—In Loch Katrine we have never put the actual measurement of the water to the test, it being too large a quantity to deal with, but in the Manchester waterworks, and in the Sheffield waterworks, and in the Liverpool waterworks, we know the exact quantity of water falling and the quantity actually discharged, and we know the loss; and it is from those returns, and from similar returns, that I have given you these particulars. The amount of loss varies from 9 to 16 inches, the average being 12 inches.

29. That is by absorption?—Yes. In Manchester we have actually collected and measured in reservoirs 33 inches in the average of two or three dry years. Out of a rainfall of $45\frac{3}{4}$ inches we have actually collected and discharged 33 inches.

30. Is that due to the rainfall, or partly due to springs?—All springs are due to the rainfall; that is measuring every drop of water which flows off.

31. Springs must be different from rainfall; you may have springs which will take the water from a gathering area beyond that in question?—Not in the district alluded to.

32. It depends upon the geological character of the district?—Yes. There are districts to which your

observations will refer, but when you are talking of a large area with large valleys, such as at the Manchester waterworks, where the millstone grit and the lower coal measures are nearly horizontal, and where the water is thrown out by shale beds horizontally, or nearly horizontally, you practically gain or lose nothing, and the observations over the whole of that district show no loss by springs. When you get to a limestone district, or to chalk, or absorbing sands, it may be as you suggest, but in coal measures, and in the primitive measures where the fissures are very small, you may reject everything of that sort.

30. What do you allow for evaporation and absorption?—We only know that we lose so much; we only know that of the rain which falls we cannot turn to useful purposes the whole quantity by a deficiency of from 9 to 16 inches.

34. I suppose that it is a difficult question to determine?—I cannot see how you can determine it. The evaporation from water is about 30 inches. The rain which falls comes down rapidly in the mountain districts, and of all which falls we only lose from 9 to 16 inches. The least amount of loss arises in the steepest districts, and where the formation is the densest, and where there are very few springs. In the Glasgow district there are scarcely any springs, almost all the water which runs off runs off in the floods. In the granite formations there are scarcely any springs, except where the granite is disintegrated and forms gravel beds.

35. Calculating that you have a plus of 48 inches, what will that area yield?—In my calculations I have not assumed 48 inches. I have no doubt that I should be justified in doing so, but I have taken 36 inches.

36. (*Chairman.*) I understand you to say that 48 inches is what is available in the Glasgow district?—Yes, at least, and what would be available in the Welsh district, because I believe that the rain would be the same, or almost the same, year by year. By these calculations I think that we should be quite safe in taking 48 inches as the net available produce of the water in this district; but in my calculations I have only taken 36 inches, and that is only three inches more than we are actually collecting and delivering in the Manchester waterworks, although the average rain will probably be 40 or 50 per cent. more in the Welsh district than it is in the Manchester district. If you will refer to pages 28 and 29 of my pamphlet, appendix B, you will find that on the first branch of the scheme, namely the red district, which mainly consists of the rivers Vyrnwy and Banw, the total acreage of the drainage ground is 66,380 acres, and that the assumed available rainfall is 36 inches, which gives a total average per day of 148,000,000 gallons odd. Then I deduct one-fourth of that for compensation to the rivers, which is 37,000,000 gallons odd, leaving for the city 111,406,000 gallons. If you look at the next page you will find that the total acreage there of the Green district is 64,000, and that there is the same amount of rain, namely 36 inches, and that the available quantity for the town, after deducting compensation, is 107,000,000 gallons odd, making about 219,000,000 gallons as the gross produce of the two districts. Then, having determined the quantity of rain, you must have storage reservoirs for the purpose of holding the water, and that question is to be determined according to the storage capacity and according to the fall of rain, and you must give compensation to the rivers. The compensation usually given in the manufacturing districts, where frequently every drop of water in dry weather is impounded in the night and given out in the day, has been about one-third of that which can be collected. In this district I have only taken one-fourth, because it is not a manufacturing district: there are comparatively no mills, and one-fourth would very materially increase the workable volume of the stream. It may be also useful to have the following information before you:—The quantity of spring water in the driest seasons from ground of this geological formation is about from one-fourth of a cubic foot per second from each 1,000 acres to about three-quarters of a foot per second; half a foot per second would be a full average quantity in a dry season. The floods which come down are enormous. I can give instances of floods, but the floods vary from 200 cubic feet per second to 400 or 500 feet per second from each 1,000 acres, as against a dry weather volume from the same area of about half a foot per second, showing that the floods are 500 or 600 or 1,000 times greater than the mere quantity of water in dry weather; and it is from these floods that the water would be stored for the use of London and for compensation to the mills. The result is that you very materially increase the natural volume of the stream in dry weather, and the beneficial flow of it for the millowners who require it for power. By impounding the water you stop the destructive floods and you increase the useful volume, and that has been the universal result wherever impounding reservoirs have been constructed upon this principle, and compensation upon this principle has been given. Then we have to provide reservoirs to meet the longest droughts.

37. (*Sir J. Thwaites.*) Do you start with any natural reservoirs?—No, with no natural lakes. The longest drought of which we have had any experience in the Manchester waterworks was for 105 days, which was a very unusual period. In a hill district like this a provision for 120 days would cover the longest drought, or the longest succession of droughts ever likely to arise. On the east of England it requires as much as 240 days in order to cover the droughts there, at Newcastle for instance; but in these wet districts where it seldom ceases raining, and where the droughts are not long, 120 days would be quite sufficient, independently of the quantity of water which may be supposed to come from springs during that period. I have provided reservoirs upon that scale, and the quantity of gallons of water per day which could be delivered from the reservoirs which I have provided would be 222,000,000 gallons for 120 days, or 190,000,000 gallons for 140 days, and this is exclusive of the yield of the streams flowing into the reservoirs during that period; if they were taken at half a foot per second for 120,000 acres it would be equal to rather more than 30,000,000 gallons a day in addition. There is therefore provision by those reservoirs for 140 days of 190,000,000 gallons, after giving compensation, and say 30,000,000 gallons in addition from the stream itself, which would make 220,000,000 gallons. Then, if you take the storage reservoirs at 220,000,000 gallons for 120 days, and 30,000,000 gallons as the produce of the stream, you have provision for 250,000,000 gallons of water. Those districts are merely selected because they are the best for the purpose and the most convenient to treat with first. The situation of the reservoirs has been selected with great care. There is one at Llanwddyn, about 750 feet above the level of the sea, which is in the Silurian formation where a reservoir of $5\frac{1}{2}$ miles can be laid out. The Llanwddyn reservoir is 1,000 acres, and it contains 1,089,000,000 gallons. At other places, in similar valleys, reservoirs have been laid out in most excellent situations.

38. What is the width of the reservoir which you say is $5\frac{1}{2}$ miles in extent?—I do not know. The capacity is the thing which you really have to deal with. It will not be more than half a mile on the average. It is a narrow valley. It is as nearly half a mile as possible, and the length is rather more than five miles.

39. What will be the depth of that dam?—76 feet is the height of the embankment. The length is really very short there. It is a very favourable place indeed.

40. (*Mr. Harrison.*) In the evidence which you are now giving are you speaking of this matter from actual sections which have been taken?—Actual sections have been taken of all these reservoirs. Then on the river Banw there are three other reservoirs, all of which have embankments 80 feet in height, and

J. F. Bateman, Esq.

6 Feb. 1867.

they are all 6 feet above the top-water level. On the river Severn, the green district, there is a situation for the very finest reservoir which I ever saw. It contains 150 per cent. more water than Loch Katrine.

41. (*Chairman.*) What is the name of that reservoir?—The Trefeglwys reservoir. There the formation is all very hard clay, and the embankment would be founded in hard clay, the outsides being composed of the driest material in order to prevent slips. The area of Loch Katrine is about 3,000 acres, and the area of this reservoir is about 1,600 acres.

42. (*Mr. Harrison.*) In talking of capacity you talk of the available capacity for waterworks?—Yes. Loch Katrine is 3,000 acres, and we have the power of drawing 7 feet from it. Loch Venechar is about 1,200 acres, and we have the power of drawing 12 feet 8 inches from it.

43. (*Sir J. Thwaites.*) Your capacity is calculated from the point of discharge?—Yes, from the lowest point from which the water can be discharged.

44. (*Mr. Prestwich.*) What is the drainage area of Loch Katrine?—About 23,000 acres, and the drainage area of Loch Venechar, which is our lowest point, is about 45,000 acres.

45. (*Chairman.*) What is the area of this reservoir?—1,600 acres, and its capacity is 2,230,000,000 cubic feet of water. The capacity of Loch Katrine is 910,000,000 cubic feet. On the lower portion, coloured green on the map, I have not surveyed the reservoirs; all the other cases which I have given are cases of actual survey and sections, but the green is an equally good district, as far as eye observation goes, in which to construct reservoirs; geologically it is the same, and as far as the site for a reservoir goes, it is an equally good district with the others. Therefore from these two districts, taking only the low quantity of available rain, which I have taken, namely, 36 inches, which I think is only three-fourths of that which I might have taken, if you add the volume of the streams, during a long drought, you have from 220,000,000 to 250,000,000 gallons, according as the drought may last, from 140 to 120 days. If it is only a 120 days' drought you have a supply of 250,000,000 gallons, if it is a 140 days' drought you have a supply of 220,000,000 gallons. But quite adjoining to this locality, and almost as convenient, lie other districts from which a very considerable quantity of water may be obtained. In the valley of the Severn, on the southern side of the aqueduct, there is a large tract of ground above the level of the aqueduct from which the water may be equally impounded as on the north side. In the valley of the Wye there is a tract of land which may be brought back by a comparatively short tunnel to join the aqueduct. Those are 44,000 acres, and that being two-thirds of the other amount they are capable of supplying about 66,000,000 gallons of water in addition. Then there is a tract of country at a level of above 500 feet underlying the summits of the hills which bound the valley of the Severn which is almost exactly 50,000 acres; the land there is capable of yielding about 80,000,000 gallons a day more, so that you have in adjoining districts an additional quantity which may be collected by proper reservoirs and conduits of about 150,000,000 gallons a day, making a total quantity of 400,000,000 gallons of water. That is a provision which I do not think that you need contemplate. If you provide the means of conveying 300,000,000 gallons, you are, I think, doing as much as may be reasonably expected. In the 250,000,000 gallons I am including the natural volume of the streams, 220,000,000 would be the storage capacity.

46. (*Mr. Harrison.*) Is that northern district so situated that it could be brought into the same aqueduct?—Yes. I have not extended my inquiries as to the actual position of the reservoirs, but I have no doubt that convenient situations for reservoirs can be found there, as have been found in other districts, and the whole of that water may be conveniently brought across the valley to this point (*pointing to the map*). I may say that I have had very large experience in constructing reservoirs, and that there is no difficulty whatever, either from the geological character or the position, or anything here to endanger the construction of an embankment. It is almost an impervious district, and the ground is so close that no water can penetrate. In all the districts (except the one at Trefeglwys, which is all clay, the bottom of the valley there being shale) the material is of the slate formation, and we find no difficulty in constructing reservoirs in a district of that sort. In the district of the Manchester waterworks, which is in the lower coal measures and the millstone grit, and which is very much fissured, we find great difficulty in that respect, and there we have a string of reservoirs, the upper embankment of which is 90 feet in depth. The second is 100 feet, and the third is 80 feet, and we are now constructing two reservoirs below that, with embankments of about 56 feet, which will make five reservoirs, filling the valley altogether for about six miles.

47. (*Sir J. Thwaites.*) Of what material are they constructed?—Of the material of the country. We construct a wall of puddled clay in the centre, the adjoining portions also clay, though not puddled, and the remainder of the best material of the country, generally shale, and the outer part stone. The inside is pitched.

48. What is the width of that embankment?—This (*pointing out the same*) is about 540 feet wide. The slopes are three to one on the inside, and two to one on the outside, and then there is the width of the top bank. This, the Manchester district, is a very difficult one in which to make reservoirs. It is the most difficult district which I ever had to deal with. We have two other reservoirs, one of 76 feet and the other of 60 feet. The height of the embankment of one of the early reservoirs made in Lancashire, the Turton and Entwistle reservoir, is 108 feet. The embankment of one of the Bolton waterworks reservoirs is 86 feet.

49. (*Chairman.*) What is to be the mode of construction of the reservoirs in this district; of what material will they be formed?—There is abundance of material. These reservoirs (*pointing to the red portion on the map*) would be constructed of clay, and the outside of the driest material, namely, shale and rock. In the others, in the bottom of the valley and the sides of the slopes, there is an abundance of clay to make the embankments.

50. (*Mr. Harrison.*) To what extent will those reservoirs interfere with any existing houses or works?—There are no works. There are no residences, except a few houses. In Llanwddyn there is a small village of 30 or 40 houses and a church which would be destroyed. In the Trefeglwys reservoir there is also a small village and a church which would be destroyed, and that is all which would be destroyed. There is not a gentleman's residence in the district, nor a manufactory of any kind until you get to Llanidloes. The district to the north-west of Llanidloes I have not included, because at the head of that portion there are some lead works, but with that exception there are no mineral workings, and none in the district to the north. At Llanidloes there is a mill, and there is another mill at Newtown, but the mill property is very small, and the mill property would be benefited, as far as mill power is concerned, by the system of compensation.

51. (*Chairman.*) Assuming that you destroyed two villages and two churches, what would you propose to do with them?—The churches, I suppose, we should have to re-erect. The villages would be paid for like the destruction of property by a railway company. They belong to somebody, and we should have to pay compensation for them. I do not suppose that there would be any difficulty about that.

52. If you destroyed a village, and did not build it up again, there would not be much use for the church?—Probably not, and the church might be transferred to another district. In the Manchester waterworks we have destroyed a village, and have left a church, which has scarcely any congregation. In the case of

the villages in the Llanwddyn reservoir I have included a cost of 3,000*l.* for rebuilding the church, and for 40 houses, which are mere cottages, 3,000*l.*, and compensation 2,000*l.* If the embankment were made water-tight the pressure would be at right angles to the slope, and therefore the whole weight of water would merely add to the tightness of the bank.

53. (*Mr. Prestwich.*) Have you gauged the streams in this district?—No, because the gauging is of no use, except the dry weather gauge, inasmuch as it is impossible to get the flood gauge unless you have almost hourly measurements, day by day, but I have gauged streams of almost entirely the same character, some in the lake districts, and also in the case of the Glasgow waterworks and in other districts of the country. In speaking of half a foot a second as the natural volume of the stream in dry weather I am speaking from my experience, and what I know to be the case.

54. Have the rivers been gauged lower down?—I do not know that they have. The river Severn is very liable to floods.

55. (*Chairman.*) Are you of opinion that there is great advantage and economy in using soft water?—Yes.

56. Why is that?—Because it produces a lather with a less amount of soap; you use less tea for making tea, and you use less coffee for making coffee. A great amount of evidence has been given upon that subject to the Board of Health, and I believe that it is reliable evidence. I can give you the actual result in Glasgow from the introduction of the Loch Katrine water.

57. (*Sir J. Thwaites.*) Have you any tables to show the quality of the water from this district?—According to Dr. Clarke's test the water is about from one to two degrees of hardness, and this is not in flood, when it is softer, and from which the great body of water would be obtained and stored, but these are the streams in dry weather, when the water is always harder. (*The witness read the following table*):—

TABLE of the ANALYSIS of WATERS collected from the Streams which are proposed to be abstracted for the Supply of the Metropolis from North Wales, by the late Dr. Robert Dundas Thomson, F.R.S.

	Total Impurity.	Organic Impurity.	Total Hardness.
	Grains per gallon.	Grains per gallon.	Degrees.
River Vyrnwy at Pont Hagel	2·60	·72	1·8
River Banw at one mile below Can-Office	2·84	1·16	1·8
River Clywedog at Llanidloes Bridge	6·80	1·40	1·1
River Severn and Afon Dulas at Llanidloes Bridge*	9·92	1·96	1·4
River Severn at Caer Sws	7·24	1·44	2·2
Comparative analysis of other waters:—			
Loch Katrine water, supply to Glasgow	2·35	·605	·8 in the loch.
Manchester water supply	3·33	·680	1·5 as supplied in the city.
Bala Lake	2·08	1·28	·8 in the lake.

* In this sample was included water from the Hafron Brook, or river Severn proper, which stream is excluded from the scheme in consequence of mineral workings at the head of the valley.

58. Was not that statement made some time ago?—But the water does not change.

59. Is there no increase of population?—No. In the Bala Lake, where the water is received from precisely the same geological district, but is impounded flood water to a great extent, the water is of only $\frac{8}{10}$ths of a degree of hardness, and that will probably be the quality of the water when impounded in reservoirs. The Loch Katrine water is ·8 in the loch itself, which is precisely the same as the Bala Lake water, and which may be expected to be the same as the water collected in reservoirs if impounded in this district. The Manchester water supply varies from $\frac{6}{10}$ths of a degree to about 2 degrees in the stream itself, and as delivered in the city it is of about $1\frac{1}{2}$ degrees of hardness. I believe that there is no better supply of water in the world than at Manchester. The water of the Clyde, from which Glasgow was formerly supplied, varies according to weather, between 7 and 9 degrees of hardness, and the water which supplies this city varies between 13 and 15 degrees of hardness. In the primitive formation, in the millstone grit formation, and in some sands, the water is soft. From chalk, from oolite, from lias, and from the new and the old red sandstone it is always hard, and taking the hardness to begin at 5 degrees of hardness I believe it is all above 5 degrees. Therefore it is of importance in selecting water for a great district that you should go to a soft supply. The saving of soap in Glasgow, after the introduction of the Loch Katrine water, which was introduced on one day and never taken from the city again, was as follows:—The manufacturers who used large quantities of soap, and who knew what their consumption was, found that they did the same work better with three boxes of soap than they had done previously with eight boxes of soap, so that they saved $\frac{5}{8}$ths of the soap previously used. I personally inquired amongst some of the large printers, and those who used water in Glasgow, and the saving varied from fully half to $\frac{5}{8}$ths, but the most general computation was that the saving was one half, and I know that the result was better bleaching and purer colours. Then, from calculations made by very careful housekeepers, they calculated that the saving by the use of the Loch Katrine water, to say nothing of the wear and tear of clothes in washing, was quite equal to the rate which they paid for water and upon the north of the river it was then 36,000*l.* a year, so that the saving to the city of Glasgow, upon a population of 360,000 or 370,000 persons, being the population upon the north of the Clyde, amounted to 36,000*l.* a year, or 2*s.* per head per annum. The reports to the Board of Health particularly dwelt upon that point; they obtained a great deal of information, and amongst the rest, information from Dr. Clarke, who invented the particular test which goes by his name as Dr. Clarke's soap test. The quantity of soap taken to produce a lather in a given quantity of London water of 15 degrees of hardness was $30\frac{1}{4}$ oz., and the quantity required to produce the same amount of lather with water of 4 degrees of hardness was $9\frac{1}{2}$ oz., which was less than one-third of the soap, the difference being 11 degrees of hardness. Amongst other inquiries they made many inquiries with respect to cooking by M. Soyer, and he went very largely into the effect upon vegetables, and found that there was an economy altogether in cooking. The result was that two-thirds of the quantity of anything which had been previously used produced as good a result as the three-thirds with hard water.

60. Do you mean after it was boiled?—Yes.

61. Take cabbages?—He goes into the question of cabbage and vegetables generally; it is interesting, and that is his result.

62. (*Chairman.*) What you mean is that it takes less soft water to boil a cabbage than it does hard water?—I mean that you get a better dish of cabbage, of a better colour and flavour, and more nutritious, boiled with soft water than boiled with hard water; and that if you make tea you get an equally good cup of tea with two-thirds of the tea, as with three-thirds. Then Mr. William Hawes, who also gave evidence to the Board of Health, he being a large maker of soap,

J. F. Bateman, Esq.

6 Feb. 1867.

in 1844 estimated the consumption of soap in London at 15 lbs. per head per annum for the wealthy classes, 10 lbs. for the shopkeepers and tradesmen, and 4 lbs. for the labourers, bringing out a result of 200 tons per week. That makes the total quantity of soap used in the year 10,400 tons, which he put at 45*l.* a ton, which I suppose is the wholesale price, making the value of the soap consumed in London 468,000*l.* Dr. Clarke in the year 1850, six years later than that, estimated the consumption of soap used in London at 12,000 tons, being 1,600 tons more than Mr. Hawes estimated it at in 1844, so that the calculations may be said to be both the same. Dr. Clarke estimated the price at 50*l.* a ton for 250 tons per week, and he calculates the soda at 10*l.* a ton; that makes for the soap 600,000*l.* a year. Since that time nearly 20 years have elapsed, the population having increased in that period 50 per cent., and soap may be supposed to have increased also, which would make as nearly as possible 1,000,000*l.* a year as the actual value of the quantity of soap used in London by the inhabitants. Now, if with soft water half the soap will do which is requisite with hard water, there is a saving in soap alone of half a million of money. I merely throw that out as the result of actual observation and consideration. I may mention that in my own house in the country I introduced about three years ago very soft water, equal to Loch Katrine water, in place of hard water which I had before, and the saving amounts to about 4*s.* or 5*s.* per head upon the household soap used in my establishment for house purposes and for washing; it amounts I think to from 3*l.* 10*s.* to 5*l.* a year, and for six months in the year my establishment consists of about 25 persons, and the washing goes on all the year round—that is in soap alone. Those who know the delight of washing in Manchester or in Glasgow in their water, as compared with the London water, will understand the difference. The Londoners and those unaccustomed to the use of soft water can hardly get rid of the soap, for all that you have to do with this water is to touch the soap and you have soap enough to wash yourself perfectly. In many other ways, in the health of the people and in the wear and tear of clothes, there are savings. It is difficult to put the matter in figures, but if they save in Glasgow some 40,000*l.* a year upon a population of 400,000, they would save in a population of 3,000,000 300,000*l.* a year, supposing the difference in the hardness of the water to be the same. In Glasgow the change is from water of about 8 degrees to water of about 1½ degree, and this would be a change in London from water of about 15 degrees to water of 2 degrees, and the saving would be proportionately greater here. I could go very much more largely into this point, but I think that that is sufficient. In the same report of the Board of Health there is the evidence of Mr. Temple, a barrister, who speaks as to the effect of the Paisley water, where hard water was done away with and soft water was substituted, and he says that there various complaints were diminished by the use of soft water. The waterworks manager in the same town gives evidence upon the same point, and he says that from experiment London water requires twice as much soap as Paisley water; and he also confirms the evidence as to the diminution of dangerous diseases.

63. (*Mr. Harrison.*) Can you give the names of any gentlemen who have especially devoted their attention to this question of the economy from the use of soft water?—Yes. You had probably better have somebody from Glasgow who would speak as to the actual result from his own knowledge of the introduction of the Loch Katrine water. I may mention that this year I have a bill in Parliament for the supply of water to Dewsbury, Batley, and Heckmondwicke, which bill is principally promoted by the manufacturers in consequence of the softness of the water. They there get hard water in their own towns, and they find the advantage of soft water to be so great that they would spend almost any money in obtaining it.

64. You have stated that the Loch Katrine water was introduced in one day. What became of the old supply; was it in the hands of the old parties to whom the original supply belonged, or did the town take it?—The town purchased the old waterworks, and took the supply into their own hands.

65. (*Sir J. Thwaites.*) Did not they abandon the old supply?—Yes; that supply was pumped from the river Clyde. The city of Manchester was in the same position; the old supply was in the hands of a private company and it was purchased, and the corporation took it into their own hands, and then the old supply was entirely abandoned. When I say that the Loch Katrine water was introduced in one day, I mean that from the time that the Glasgow people received the Loch Katrine water it was never withdrawn. In Glasgow the new outlay for water was about 1,000,000*l.*, besides the purchase of the old companies, which made the whole cost about 1,600,000*l.* The inhabitants got their water at the same rate as they had previously paid the water company, and therefore they paid no more for their water although they laid out 1,000,000*l.* The saving in pumping, and the increase in the population, and the demand for water were such that after the first two or three years, during which they did pay a little heavier rate, the rate fell to the same price as it had been before the introduction of the new water, and from this time it will be lower. If by the use of that water they saved a sum equal to their whole rate they saved about 40,000*l.*, which at four per cent. was equal to 1,000,000*l.*, which they put into their pockets.

66. (*Sir B. Phillips.*) By whom was that undertaken?—By the corporation.

67. How was that 1,600,000*l.* raised?—By borowing on the security of compulsory rates upon the whole property of the city.

68. Repayable in what way?—Repayable within a given number of years by a sinking fund, but upon debentures raised on the security of compulsory rates upon the whole property of the city. Everybody was obliged to pay, and in the case of the domestic rate there was an unlimited rate on the northern side of the city. A limit was put upon what was called the property rate of I think 2*d.* or 3*d.* in the pound.

69. Do you say that they raised that money at four per cent.?—In Glasgow it was about that amount or rather more. In Manchester the average rate of interest upon the debenture debt of the waterworks which belong to the corporation, and which cost about 1,500,000*l.*, is 4*l.* 0*s.* 10*d.* per cent.

70. How is that money to be repaid?—You pay four per cent. upon the actual expenditure, and then you have the working expenses, and you levy a rate which will be sufficient to meet those two charges.

71. I understand you to say that the Manchester people pay no more for their water now than they did before?—The Manchester people pay a great deal less than they paid formerly, and in Glasgow they pay no more than they paid formerly.

72. (*Mr. Prestwich.*) Can you give us an exact analysis of the water which you propose to appropriate?—I cannot, but it is from the same geological formation, and the water would be the same. I can give an exact analysis of the Glasgow water which comes from the same formation, and also of the English lake water which comes from the same formation.

73. (*Chairman.*) You state that the streams are to be compensated, and that the measure of compensation is well understood?—The principle of compensation is that which I have described in the rivers in Lancashire and Yorkshire and the north of England. Generally there, in consequence of the streams being so much used, and the streams being small, the millers have the power of impounding the night water, and therefore making the whole available during 12 hours, and their compensation is about one-third of the water which is collected. Here, where the mills are very trifling and the stream is very large, and where therefore the millers cannot impound the night water, one-fourth would be a most abundant compensation;

it would increase the volume of the stream in dry weather three or fourfold.

74. In this district are there any fisheries of any kind?—There are scarcely any fisheries. The salmon are stopped by weirs which exist, but since this project became known there has been a stir amongst the fishers; they have denounced it as being a scheme which is going to destroy them. I have, however, a report which was sent to me the other day which shows that no fisheries exist at all now; but there is no reason whatever why the fisheries should be injured. The plan adopted in Scotland for allowing fish gaps and fish ladders may be adopted here, in the case of all the weirs. We have various fish ladders at Loch Venechar, upon the Glasgow waterworks, and we have another at Loch Katrine, and the salmon go up these weirs as they do on the river Forth and other places. There would be no difficulty in arranging the works so that the fisheries might be entirely protected and in fact improved.

75. Do you diminish the quantity of water which would be running in these streams at any particular period of the year?—Yes, in flood we do. The whole principle is that of impounding the floods; and, therefore, immediately below the reservoir, instead of there being a flooded stream there would be an equable stream. Of course a little lower down than that other streams come in and make the river liable to floods, but immediately below the reservoirs there would be a constantly equable flow, instead of a flood at one time and a drought at another time.

76. Are you not aware that those floods are of great benefit in large fishing rivers?—I am. I know that the fish wait for the floods, or, as they are called in Scotland, "spates," in order to go up, but we should only diminish the floods in the lower part of the district, and should not destroy them. There would not be as great a flood as there was formerly, but still a sufficient flood to carry the fish up. But I presume that the fish wait for floods, because in many parts the fish could not go up without them.

77. That is not so?—I have heard so much about salmon fisheries in Scotland that I thought that that to a great extent was the fact in many rivers. The theory (and perhaps it is a correct one) is, that the fish will not go up except there is a spate coming down, but without any difficulty you may make a flood here at any time, if you only get a certain quantity of water. You may make a flood instead of giving the water in regular quantity, and there would be no difficulty in making stairs by which the fish could go up there past the reservoirs.

78. (*Mr. Harrison.*) Is not one of the objections raised by gentlemen who fish with a fly?—There is no difficulty in fishing with a fly. You could produce a better reservoir to fish in and finer fish.

79. You can hardly get the fish up 80 feet?—Yes, you can get them up 80 feet as well as up 8 feet; it is only a greater number of jumps for them. For instance, they go up 80 feet now in five miles, and you can make them do so by a great number of jumps in a shorter distance.

80. (*Chairman.*) Do you imagine that the salmon would go up as readily into your reservoirs, in comparatively still water, as when they were meeting the natural force of the stream?—Just the same. They go into Loch Venechar in great quantities up the salmon ladders, and they go through Loch Venechar. They scarcely ever go into Loch Katrine because there is no gravel bed for them to spawn upon. Loch Venechar is a salmon loch, and Loch Lomond, and also Loch Ness are salmon lochs. You will also consider that where the lakes are large in area in proportion to the drainage ground they are so many regulating reservoirs which destroy the floods.

81. Will you describe Loch Lomond and Loch Venechar, and those lakes; would they have the same description of bottom as you would have?—The salmon do not spawn in the lakes.

82. Would the salmon be likely to be as well off in your reservoirs as in a natural lake?—The trout would be better off, because in newly formed reservoirs there is an enormous amount of food, afterwards of course they become just the same. A lake made by a natural obstruction like a great rock across a valley is in all essential points the same as where there is an artificial obstruction.

83. (*Sir J. Thwaites.*) Could salmon get up 80 feet?—I should not expect them to make 80 feet at a jump. The salmon ladders are made with a slope of about 1 in 10, and the salmon will run up 1 in 10 or 1 in 6 for a very considerable distance, and there are weirs such as the Deanstone weir on the river Forth, which has about 16 feet of fall. There is a salmon ladder there, and logs of wood are put across, and the salmon run up the whole ladder at once. It would be only five times that here. Here is a salmon ladder at Loch Venechar (*producing a drawing*), and the salmon constantly go up that.

84. (*Col. Harness.*) What is the fall of that?—12 feet 8 inches, and when that reservoir is drawn below the top of the lake they cannot go up that weir. Then we make a succession of ladders of different heights, and they go up whatever the height of the reservoir is. Within these walls there are four different ladders at different heights, according to the height of the water in the lake, and the salmon go up there constantly. The outlet of Loch Katrine is a mere gorge in a rock, and there are merely two heights of ladders. In Lock Venechar there are four heights of ladders, and the salmon go through a sluice with a depressing door, and they go up as easily as possible. That does not meet the objection which his grace makes to my statement that a flood is the only condition of a stream in which a salmon will run.

85. (*Mr. Harrison.*) Supposing that the water inside this reservoir were lowered to the extent of 40 feet below the surface, would you propose sluices which should come through?—Yes, if necessary, that could be done. I have made drawings for that purpose in some of the cases in Scotland, but there is no reason why the river itself in its natural quantity in dry weather should not be conveyed round the reservoir, and having got up the stairs into the new channel the fish would be carried right away into the stream above.

86. You in fact would make a byewash?—Yes, which is a very common and very desirable mode of using the water.

87. Do you know whether the upper portions of the rivers which you are proposing to enclose are good spawning grounds now?—They are not.

88. (*Chairman.*) Can you state why?—Upon that point I can only refer to the report of a gentleman who has made a recent inspection of the whole streams, and who has particularly denounced this project; and from his report the progress of the salmon is now opposed by existing weirs.

89. The point is, whether the rivers in this district are or are not good spawning grounds?—I do not know. I am not a salmon fisher, but I should think that they are good spawning grounds. You want a gravel bottom for spawning ground, and although that is not the general characteristic of streams from the Silurian formation, yet I should think that there is a sufficient amount of ground of that description to form good spawning ground. The rivers will be very much of the same character as the rivers which flow from the southern end of the Grampian Hills in Scotland.

90. You are possibly aware that some of the best spawning grounds in Scotland are in the smallest streams, through which in the month of August you could walk without wetting your shoes, and which towards the end of the year have much more water in them?—Yes, I am quite aware of that, but it depends upon the character of the bottom, whether it is a gravel bottom, or a mud bottom, or a hard rock bottom; and the character of the bottom depends upon the character of the formation from which the stream comes.

91. (*Mr. Harrison.*) Is there an association in that part of the country for the preservation of the salmon

J. F. Bateman, Esq.

6 Feb. 1867.

fisheries?—I believe that one has been recently formed, but all that I know about the fisheries is from a report which I have seen.

92. By whom?—I forget the name of the gentleman.

93. (*Chairman.*) You only know that he condemns your scheme?—I only know that he says that it is the most disastrous thing which was ever conceived; at the same time the report speaks for itself, and I believe that it shows that at all events we do not destroy anything in existence, but only something which in anticipation he may make to exist.

94. You are probably aware that the question of salmon fishing in that part of the country has been a subject of considerable discussion?—I am quite aware of that, and I should be very sorry to project a scheme which should do any mischief, if it could be avoided; but as to the fisheries I am quite satisfied that we can make provision for all the fish going up the stream.

95. (*Mr. Harrison.*) By means of a byewash you might be able to take the salmon past?—A long slope from the waste weir would enable the salmon to go up; if you made a slope of 1 in 10 they would go up to any distance, if you gave them a resting place here and there. I had occasion to consider that question before I executed the Glasgow waterworks.

96. (*Chairman.*) Are there salmon rivers between your Glasgow waterworks and the city of Glasgow?—The stream from Loch Katrine runs into Loch Achray, and from Loch Achray into Loch Venechar, and from there it is the river Teith. Above Loch Venechar it is a very excellent salmon river, and just as good a salmon river as it was before. The salmon stairs are now at the outlet of Loch Venechar.

97. How is the water taken from Loch Venechar?—Loch Venechar is a compensation reservoir, and the water from there is discharged for the purpose of increasing the stream in dry weather, and compensating the millowners.

98. The position of the salmon in your Glasgow scheme would not be upon all fours with the position of the salmon, if you carried out the scheme of bringing water from North Wales to London?—It would be precisely the same except as to altitude, because the salmon can go upstairs at an embankment put across a lake, which is nearly the same thing as an artificial reservoir. The water which is taken to Glasgow is abstracted from the river Forth and turned into the river Clyde, and the water which would be abstracted from the Severn would be turned into the river Thames for London. The only difference would be that there would be higher embankments.

99. (*Mr. Harrison.*) To what extent have you the power of lowering the water in Loch Venechar?—Twelve feet 8 inches.

100. What would be the level of your discharge pipes above Trinity high water?—Four hundred and fifty feet within a few feet. I think that there are a few feet of difference. It is 435 feet I think in one case, and 450 feet in the other.

101. Would that be a sufficient height in bringing water to London to give a constant high level service?—It would give us a fall of one foot in a mile on the average. The distance is 183 miles, and that would be 183 feet. Deducting that from 450 feet you have about 270 feet in round numbers above high-water mark.

102. At what distance from London would that be?—At Stanmore, it would be about 10 miles from Cumberland Gate, Regent's Park. You cannot go beyond a certain height, because the intervening country between Bridgnorth and London limits you as to the elevation to which you can go. From the reservoirs to Bridgnorth there is no difficulty; you go along the hill sides and through the hills by short tunnels.

The witness withdrew.

Adjourned to to-morrow at 11 o'clock.

Thursday, 7th February 1867.

PRESENT:

HIS GRACE THE DUKE OF RICHMOND IN THE CHAIR.

Sir JOHN THWAITES.
Colonel HARNESS.
Alderman Sir BENJAMIN PHILLIPS.
THOMAS ELLIOT HARRISON, Esq.
JOSEPH PRESTWICH, Esq.

JOHN FREDERIC BATEMAN, Esq., further examined.

J. F. Bateman, Esq.

7 Feb. 1867.

103. (*Chairman.*) Will you describe to us the mode in which you propose to convey the water to London from the district which you have selected?—I am doubtful whether I have sufficiently explained the mode of collection, and the manner in which the water would be collected in the reservoirs, so as to make you quite clearly understand the whole of that matter. I doubt whether I made you clearly see the probability of the fall of rain which I have assumed. I only take 36 inches out of 48 inches which I believe I could collect. I have since yesterday prepared a table. I have taken various gauges which I might call mountain gauges from their elevation, or from their position amongst the mountains, which have been selected as nearly parallel cases as the means afforded in Wales and in the Lake district, in order to deduce from that information the available quantity of rainfall. I gave you yesterday the returns of nine gauges in Wales, as showing an average amount of fall in the year 1865, which was the driest year of which we have any record, of 59¼ inches. I also gave you the average of nine gauges in the Cumberland Lake district as 59·89 inches. The height of those nine gauges in Wales varies from 70 feet to 1,140 feet above the level of the sea, that is the highest gauge which we have. The Lake guages vary from 250 feet to 3,200 feet. Up to a height somewhat exceeding 2,000 feet in a mountain district, apart from local circumstances, which may create a great fall of rain in a particular valley, it is ascertained from observation that the rain falling is constantly upon the increase; it is less upon low ground than upon high ground, and less upon high ground than upon ground higher still, till you get to an elevation exceeding 2,000 feet, and then it diminishes. I could not get returns of similar altitudes in Wales, but I took from my knowledge of the country a fair comparison between the two. Since yesterday I have made out returns for 1866, and I find that the nine places which I gave you in Wales give an average of 77⅓ inches for 1866, the least rain in those places being 51 inches, and the highest rain being 114½ inches in the course of last year.

104. (*Sir J. Thwaites.*) If I remember rightly, the smallest fall was on the area which you propose as your gathering ground?—The smallest fall was at Rhayader, at the head of the Wye, but I have no gauges at all upon the gathering ground except at Llanidloes, that is directly at the foot of the hills to the east of Plynlimmon, the others are proximate

districts. Then in the Lake district the average for last year of the same nine places as I before gave was 84·66 inches as against 77⅓ inches, the lowest rain in those nine places being 62⅔ inches at Keswick, which in point of position may be said to represent as nearly as possible Llanidloes, and the highest being 102½ inches, which was at Wasdale Head, a favourable place, and which I selected as being as nearly as possible in the same position as Beddgelert in Wales, which is 113½ inches; that shows a remarkable similarity, so remarkable that the deduction is inevitable that there is quite as much rain, or perhaps rather more rain, falling upon the Welsh hills than upon the Lake hills. The circumstances of the position and the mode in which the valleys lie to the sea, and the manner in which they are affected by the clouds are all similar; but there is one point which I do not know whether I sufficiently dwelt upon yesterday, which is very important in considering the probability of collecting water when you have not the actual returns. If you could suppose a ridge exceeding 2,000 feet high you would have comparatively little rain on the east side, it would stop nearly all the rain clouds from the west and the water would be precipitated on the westerly slopes. In the north of England it is well known that a westerly wind is a dry wind on the coast of Northumberland, while it is a wet wind on the west coast, and that a wet wind on the coast of Northumberland is a dry wind in the western portion of the country, although the hills there are not so high as absolutely to exclude the rain. But where you have a range of mountains, the summits of which measure upwards of 3,000 feet, with depressions in the ridge, you get the largest amount of rain in the valleys to the east of those depressions. Wherever the rain-cloud can be gorged up a narrow valley and pressed over a depression like Stye Head, into the head of Borrowdale, then on the easterly side you get by far the largest portion of rain; and with this in view this district is worth explaining a little further. The general course of the ridge is in this direction (*pointing to the map*). Snowdon is the highest point. This is the general direction in a tolerably regular line from south to north. In that ridge there are various depressions, and I believe that if gauges were placed from Portmadoc up to Beddgelert, and then on to Capel Curig, you will find there as large an amount of rain, or nearly so, as you do in Borrowdale. Then there is another depression which runs up from Dolgelly, and which runs down to Barmouth; there is a very large amount of rain there. Then there is another depression at the river Dovey, and there is a gap there, and the water would be precipitated just over this side (*pointing to the map*). On that we have a gauge recently put, which in three months shows 24 inches of rain. Then there is another depression in the sources of the river Dovey here, and another here (*pointing out the same*), and then we get to tolerably high land to this point, with one or two depressions, so that on this easterly side, if properly examined into, rain gauges may be expected to have a very large quantity of rain. That is the easterly side of the general ridge of mountains extending from Snowdon to Plynlimmon, and there is there a large quantity of rain. As you get away from the easterly side the quantity of rain will diminish. I was merely anxious that that should be clearly understood, because in referring to any mountain district you will find that that is so. If necessary, I can show you rather interesting tables which I took some time ago right across England from Liverpool to Hull, over the Manchester waterworks drainage, and over the Halifax waterworks drainage. The Liverpool waterworks afford a very good illustration. The rain at Rivington in the Liverpool waterworks district was 50 inches. The Bolton waterworks are in the first trough over the hill to the east, the trough running pretty nearly south and north. The westerly winds impinge upon the westerly slope of the mountains which form the drainage of the Liverpool waterworks, and in the average of two years the rain there is about 48½ inches. The rain at Belmont in the Bolton waterworks is 53 inches, and that is going eastward. The next trough is the valley from which the Blackburn waterworks are supplied, and there you have a mean of 42 inches. On the first slope of the hill, which is on the westerly side, you have about 48½ inches, then 53 inches, and then 42 inches. Then when you get away over the mountains and right down into the east, you get down to about 30 inches. The Manchester waterworks are formed in a mountain range, the Penine chain of hills, lying between Manchester and Sheffield, commonly called the Backbone of England. The rain at Manchester in 1859 was 38 inches in round numbers. Going eastward the rain at the Denton reservoir, our first reservoir, which is 300 feet above the sea, was 34 inches; at Newton it was 35 inches, and going a little further eastward it was 33 inches. All these places are upon the plain, or nearly the plain. Then we come to the foot of the hills and we get 46⅓ inches. Higher up at the head of the valley, on the west side, we get 53⅓ inches, then 57·64 inches a little further towards the head. On the east side, just over the summit, we get 58½ inches. At the reservoir of the Sheffield waterworks, which is is on the hills more to the east, we get 46 inches. At Penistone we get 39 inches, and at Sheffield 25 inches, showing that the rain is larger on the west than it is on the east; that it increases as you get up to the top, and that it rapidly diminishes as you get to the east. On the line of the Rochdale canal, which also crosses the Backbone of England, in the same way in the year 1848 at Rochdale, which is at the foot of the hills, you get 39$\frac{7}{10}$ths inches. At Whiteholme, on the top of the hills, you get 66$\frac{7}{10}$ths inches. At Blackstone Edge toll-bar you get 67½ inches, and on the east side 66 $\frac{6}{10}$ths inches; but those last three places are almost entirely upon the summits of hills not more than 1,200 feet high. Then when you get to Sowerby Bridge, which is at the easterly foot, though comparatively in the hills, you get to 32·27 inches; and I have a return of the rain at Halifax in the same year, which would be less than that. Then I may refer also to the case of the Glasgow waterworks.

J. F. Bateman, Esq.

7 Feb. 1867.

105. (*Mr. Harrison.*) Are those facts in the form of a table which you can put in?—Yes; I will give in the whole of these tables.

106. What is the summit of the range in the case under notice as affecting the stoppage of the rain clouds?—There are, I think, depressions as low as 700 feet. If you will be kind enough to look at the map at the end of my pamphlet on this subject you will, I think, see them all. Just to the west of the highest proposed reservoir will be found a summit marked, which is 2,050 feet. Then coming southward there is 1,937 feet; then 1,981 feet; then there is a depression of 750 feet; then coming on further south you get an elevation of 1,651 feet; then you get a depression of 800 feet at the head of one of the branches of the Dovey; then you rise again to 1,475 feet, and then you get to the head of the drainage, a little north of Plynlimmon, which is 1,750 feet, and then you get Plynlimmon itself, which is 2,463 feet. Looking at those depressions you ought to have a very large deposit of rain about the centre, following up the valley of the Afon-Dyfi at about that point (*pointing to the map*). If you will be kind enough to turn to the rain returns for the last three months of 1866 you will find that the rain in the months of October, November, and December was 24$\frac{8}{10}$ths inches.

106. At what level?—I have not quite the level of that gauge. The highest return here is on the hills at a height of about 2,000 feet. That is to the east of the Aran Mowddy mountain, and then at the head of the Llanwddyn reservoir, which is about 700 feet, the rain was 16$\frac{3}{10}$ths inches. Then on the hills above Llanidloes, immediately to the east of that upper proposed reservoir under Plynlimmon, the rain was 24$\frac{9}{10}$ths inches, and at Carno in the valley the rain was 12⅓ inches, showing even in that space the rapid decrease which takes place to the east. The average rain, taking the highest and the lowest together, would be about 19 inches on the mean over the whole of that district in three months. I merely wanted to point

J. F. Bateman, Esq.

7 Feb. 1867.

out that in order to show the mode in which the rain is distributed, and that it does not do to deduce the average rain, except with due regard to the physical circumstances of the country.

108. (*Mr. Prestwich.*) What number of days' rain fall in 1865 in this district?—I have not complete returns on that subject, and I have not the number of days on which the rain fell. Many of these are mountain gauges, and we have to get men to make an excursion once a week to take the rain on them; many of them are in out of the way places. Everybody knows Loch Katrine and Loch Lomond, and the district about there, and will remember that to the west of Loch Lomond there are very high mountains in Argyleshire, which form barriers to the rain-clouds which are brought from the Atlantic. We also find that every successive trough or valley to the east has a diminished quantity of rain, and almost every successive range of mountains has a diminished quantity of rain going from the west to the east. Taking the first great valleys you have the Loch Long valley, which runs up to near Tarbet, then you have the Loch Lomond valley, and then the Loch Ard valley, going to the east, which lies on the east side of the Ben-Lomond range, then you have the valley of Loch Katrine, and then you have the valley of Loch Lubnaig. The drainage ground of the Glasgow waterworks is in the valley of Loch Katrine and Loch Venechar that lies to the north and north-east, and is hemmed in by mountains varying in height from about 2,000 feet to nearly 3,000 feet. That is shut out from the south-west by hills immediately adjoining Loch Katrine, which vary from about 2,393 feet to 2,514 feet, with depressions of not more than 500 feet above the level of the sea. Then go to the south-west again to the Ben-Lomond range; Ben-Lomond itself being 3,192 feet high. The rain on the hills upon the easterly side of Ben-Lomond, but on the flanks and the spurs of the same range of mountains, in 1854 was 109 inches at an elevation of 1,800 feet. On the hills between Loch Ard and Loch Katrine, which is the next successive range of hills to the east, at an elevation of 1,500 feet, the rain was 67 inches. On the hills near Glen Finlas, at an elevation of 1,800 feet, it was 62 inches. In 1857 the rain on the first ridge was 85½ inches, on the second ridge 74 $\frac{2}{10}$ths inches, and on the third ridge 48 $\frac{3}{10}$ths inches. In 1859, two years afterwards, it was 92 inches, 85⅓ inches, and 48 inches, and so every year all through. That shows the importance with reference to the collection of water of bearing in mind that it does not do simply to go to hills, but that one range of hills will yield a larger portion of water than another, although they may be in the same general locality and of the same general height. Then I have returns showing the increase of rain towards the heads of valleys, and showing the effect of passes in mountains, and a variety of returns, all of which tell the same story. It would be tedious to follow the matter through, but I shall be very happy to give in all these returns; they are all interesting and valuable documents. I have thought that it was necessary to draw your attention to these facts because in this particular district, in consequence of its being almost uninhabited (there is not a single resident gentleman that I know of in the whole of this district of Wales), there have been no meteorologists and no meteorological observations; the only observations which have been taken have been taken by some spirited individuals during the last three or four years, and from those returns, which are published by Mr. Symons, are the returns which I have given you of the proximate gauges. In the district itself, with the exception of Llanidloes, the only returns are those which I have given you within the last three or four months, and which I have had taken myself. From the actual fall of rain during the same period being as nearly as possible the same as in the Lake district and in the Loch Katrine district, we may fairly deduce that we shall have the same amount of rain in the one district as in the other; that rain in the driest year would leave a net available produce of 48 inches. I have assumed 36 inches as being a perfectly safe quantity, and have provided storage upon that footing. The storage then becomes the measure, inasmuch as it will be quite clear that the quantity of rain falling, and which is capable of being collected, being greater than I have assumed storage for, the measure of your delivery must be governed by the period for which the store will last during the longest drought which you can provide for, added to the natural quantity flowing down the streams during that period of drought. Of course after the rain has run off, all the water remaining in the river is from springs only, which gradually decrease according to the extent of the drought; but assuming half a foot a second, which is my experience, from 120,000 acres or 60 feet a second that is rather more than 30,000,000 gallons of water a day. The reservoirs are capable of supplying for 120 days consecutively 220,000,000 gallons, and if you add to that the natural stream during the same period viz., 30,000,000 gallons, you have 250,000,000 gallons as the produce from this district, which I have particularly examined.

109. (*Col. Harness.*) Those 30,000,000 gallons you would have to give to the watercourse, would you not, you could not avail yourself of them?—Instead of 30,000,000 gallons, which is the average of a drought, we should give a regular quantity of between 70,000,000 and 80,000,000 gallons to the river, so as to double the volume of the river in dry weather.

110. During a drought must you not give to the watercourses from which you have impounded the water the whole of those 30,000,000 gallons, and something besides?—We should give as much again; what I have given you as the supply to London is the residue. If you will refer to pages 28 and 29 of my pamphlet you will find that the quantity of water which is assumed as available, and as to be taken to the city, in the first table is 111,000,000 gallons a day; that line comes after the preceding line which shows the amount which will be given to the rivers, which is 37,000,000 gallons. If you take those two tables together you will find that they represent 218,000,000 gallons for the city and 73,000,000 gallons to the rivers. Now if the average of a drought is only 30,000,000 gallons the rivers will be 2½ times provided for by giving 73,000,000 gallons.

111. One is a calculation based on the rainfall, and the other is a calculation based on the retaining power of the reservoir?—Yes.

112. Your reservoir will contain such a quantity?—Yes.

113. But from that quantity besides what you give to the city you must give compensation?—Yes.

114. Therefore, if I understand you rightly, your reservoir would contain that number of days supply?—The reservoirs contain a supply of water for compensation at that rate. If you will divide the total amount of storage by so many days you will find that it gives 222,000,000 gallons for the city, plus the quantity for the rivers; that is plus 73,000,000 gallons odd for the rivers. In giving that quantity to the rivers we are giving it in lieu of an irregular stream which on the average of a drought would only be about 30,000,000 gallons.

115. (*Chairman.*) So that the rivers are benefited to the extent of 40,000,000 gallons?—Yes; the dry weather amount of the rivers is about doubled, and therefore the available mercantile power of the rivers will be doubled; they will have a regular equable flow during a drought, which will be double the average flow of a drought, and will be perhaps four times the minimum flow of a drought; they will have that quantity day by day instead of having an irregular supply. Then with reference to the collection of the water, of course you cannot always find a reservoir upon a stream quite large enough to hold the water of that particular stream. In another valley you may be able to find a reservoir which is more than sufficient for holding the water of its own district, and in that way the water may be conveyed from another district, and in that manner the reservoirs have been laid out. The upper red mark, the Llanwddyn reservoir will not only

hold its own water but will receive the drainage of the next valley, which is conducted by a watercourse large enough to convey nearly all the produce of the district, and the watercourse has been estimated upon a scale of flood of about 20 cubic feet per 1,000 acres, which is a considerable flood, but not the maximum. 20 feet per second from each 100 acres for 24 hours duration of flood is a very heavy flood. The water from that reservoir I have allowed to flow down the river to a point a little below Llanwddyn, and from there it is taken to the next river, to the next valley to the south, and communicates with the water collected in reservoirs in that valley, and from that point the water is taken to London. In the drainage which is coloured green there is a magnificent site for a reservoir at Trefeglwys, into that the water from the river Carno will be conveyed, and a portion of that coming from the south of that reservoir will also be conveyed by a large watercourse from the lowest part coloured green. I have not yet had the most southerly portion surveyed for reservoirs, but I believe that reservoirs are capable of being made quite as large as necessary, and in very good situations in that district. The discharge pipes of the northerly portion will be at the level of 450 feet above ordnance datum.

116. (*Mr. Harrison.*) That is at Rhyd-e-Gro?—Yes. From that reservoir at Rhyd-e-Gro the discharge pipe will be 450 feet above ordnance datum. At the Trefeglwys reservoir it is 440 feet. The conduit from thence is a little the longest, but there is a sufficient fall in both of them to convey the water to London. Then I propose to deliver the water at reservoirs to be made on the slopes of the hills, or on the hills near Stanmore near London.

117. With regard to the summit level, the greater part of it ranges considerably above the 1,000 feet and up to 2,000 feet?—Yes, the great bulk of it.

118. Comparing that level with the levels of the hills which you have spoken of in the Lancashire district, are they not a great deal below that level?—A very great deal. The summit level of the ground forming the drainage ground of the Manchester waterworks is about 1,900 feet, but the general level of the hills is about 1,500 or 1,600 feet. The mean level will probably be 1,000 feet.

119. Assuming that where you have 700 and 800 feet in passing through these gorges you have a large rainfall on the east side, would it be purely local, or do you assume that it would spread right and left after passing through?—In the rain returns which I have given you the highest returns are upon elevations of about 2,000 feet. There is no doubt that the quantity of water, which is dependent very much upon its being forced through a gap, will be local, but you will find by Dr. Miller's observations in the Lake district that the rain rapidly increases up to a contour of 2,000 feet, and then rapidly diminishes up to the height of Scaw Fell Pike, which is, I believe, 3,150 feet. The mere elevation of ground will increase the deposit of rain.

120. In fact, the whole contour of the country being high really affects the height of the rain clouds?—Yes.

121. The rain clouds have not so much reference to high-water mark as to the general features of the country?—Just so. If the elevation of the country lies within the region of the rain clouds, which may be said to extend to about 3,000 or 4,000 feet, the greatest portion of deposit within that range takes place at from 700 to 2,200 or 2,300 feet. If the mass of the gathering ground lies within that zone, setting aside local circumstances, that will be the elevation which will give the greatest quantity of rain.

122. From your experience of all parts of England, being obliged in this case to arrive at a conclusion by analogy, are you satisfied in your own mind that you have quite sufficient facts to justify you in your calculations upon the matter of rainfall?—Yes, I should consider myself quite justified in assuming 48 inches as certainly collectable and available, but in order to do that I must make larger reservoirs than I have estimated for. I have more rain than I have reservoirs for, as I have laid out the scheme, and as the estimate is that to which I must refer, it is based upon reservoirs capable of collecting and discharging 36 inches, or thereabouts, in addition to the natural stream during a period of drought. If we take 220,000,000 gallons, and add 30,000,000 gallons to that quantity for the natural volume, which is about one-eighth more than the 36 inches, say $4\frac{1}{2}$ inches; that is an actual collection and discharge of $40\frac{1}{2}$ inches.

123. A question was suggested yesterday as to the fisheries, and that these reservoirs would cut off the spawning ground. If you will refer to the green portion of this map, which really is the Severn proper, practically your reservoir cuts off a very small portion of all the different streams branching out of the Severn at that part?—That is so.

124. Taking it again when you come to the red part of the map, there are all these streams branching out and you only intercept a very small portion?—That is so. The river may be restored to a salmon-passing condition by a bye-channel all the way down from the head of the reservoir to the embankment, and then by a long sloping channel to the river again. For instance, supposing that you made a channel of so gentle a declivity that the fish would run up, if you discharged a sufficient quantity of water for the purpose, which would be a part of the compensation water, you could do that; and supposing that you made a series of leaps of no more than 3 feet each, with a deep pool between, the salmon would get up 1 yard in say every 20 yards. But salmon, if they must jump, require a depth of water to jump from. They depress themselves perpendicularly when they are about to take a leap, and strike the water violently with their tail, which enables them to leap, and unless they have a sufficient depth of water they cannot leap.

125. On that point has it ever occurred to you that as your byewash would commence at the very highest point of your reservoir, assuming your reservoir to be lowered 10 or 15 feet, the salmon would almost naturally go into your reservoir, and if they did so how would they get out?—It might be so arranged that when the reservoir was full they could run into the reservoir, or that when the reservoir was down they could go into a side channel.

126. You would stop them at the high point?—At the upper end they would go up the stream to spawn; they would not stay in the lake.

127. How would it be in coming down?—You might stop them from doing that at a certain season of the year. I believe that they go up and down at almost all seasons, more or less, though they generally go up at one season and down at another.

128. You propose to take a large area of water which no doubt would affect the floods in the Severn. Comparing that with the watershed feeding the Severn we will suppose that you take down to Shrewsbury, can you give the watershed which still supplies the Severn down to that distance?—We affect in round numbers 125,000 acres, and looking at the map and comparing the coloured portion with that which would remain untouched as far as Shrewsbury, I should think that we should have four times that amount, or say about 700,000 acres, of which we should affect about 120,000.

129. Do you think that your abstraction from those 125,000 acres, taking it to Shrewsbury alone, would at all practically affect the question of the spates and floods at that point?—It would make big floods into spates; that would be the effect. We should impound of the floods down to Shrewsbury probably one-fifth portion of the district, and if we did that we should lessen the floods by that proportion, or if we impounded the floods by one-fourth we should lessen the floods by one-fourth. One of the most injurious features of the Severn is its excessively heavy floods.

130. I am looking at the matter as a salmon question?—We could always, if need be, if the fishery question were so important as to render it necessary, make an artificial spate or assist a spate at any

J. F. Bateman, Esq.

7 Feb. 1867.

time by a little outlay in reservoirs for that express purpose. Immediately below almost every stream which we affect there are other streams coming in, which would swell the river to the condition of spate in heavy rain.

131. It appears to me that the large watershed which is totally uninterfered with is so great that it will supply plenty of flood water for the whole of the Severn, particularly in the lower parts of it?—If you take the Rhyd-e-Gro reservoir we should intercept the water of this district (*pointing to the map*). Immediately below that there is the whole of this district (*pointing out the same*) which we do not affect. There is the river Vyrnwy running down, and all these streams (*pointing out the same*) would run down, and they would be unaffected; they would be spawning grounds, and would be accessible to fish.

132. I would suggest to you that you have given very important information in this first map, which gives the whole of the water area of the Severn basin down to Tewkesbury. Having that particular object in view, if you could divide it into two or three different districts it would be important?—I will do so. In the Fishery Report, which I referred to yesterday, and which I had not then with me, written by Mr. Alexander Miller, and dated Chepstow, January 14th, 1867, he gives a long report.

133. (*Chairman.*) Who is Mr. Miller?—I do not know but he is employed by the Board of Conservators of the Severn fishery district to examine and to report upon the subject; he goes into a great many particulars. He says, "The inspectors of fisheries in "1861 report that the area of the catchment basin of "the Severn is 4,437 square miles; the length of the "Severn from its source to the sea 178 miles, and the "length of the tributaries 450 miles, together 628 "miles, but this is exclusive of small streams. I have "walked over and inspected these tributaries to the "extent of 404 miles, and have found in them some "of the finest mountain streams of pure water with "gravel fords, and containing the most superior "spawning grounds that could be found anywhere. "But of these 404 miles only 80, as I have before said, "are ordinarily accessible to the parent fish, the remainder being cut off chiefly by insurmountable "weirs, or destroyed by pollutions. The consequence "is that the parent fish have been deprived of their "natural breeding grounds, and compelled to deposit "their eggs in unsuitable places, in deep currents "where the eggs cannot be incubated, or, if hatched, "the young fish would to a great extent be devoured "by other fish, or be lost and destroyed by flood "waters. We may assume that the proprietors formerly possessed a property of some value in these "streams which they could lawfully protect and fish, "and that the mill weirs at various periods have destroyed the value of these fisheries by the erection of "insurmountable barriers across the rivers without "any compensation to the owners, until at last out "of 668 miles there are only 80 miles of breeding "grounds left to which the salmon have access." The river may be said to be not now a fishery river, or scarcely so, if this is the description of it. The great obstruction to the passage of fish is evidently the mill weirs, and Mr. Miller mentions one case of a weir 15 or 16 feet high, where the salmon attempted to leap and were hurled back with violence. Now it would be a very simple thing, and a very important advantage to the river, if those weirs were so made that the fish could pass them, and any injury which we might be supposed to inflict could be a great deal more than compensated by making such arrangements as that the fish could pass at every one of the weirs. Then Mr. Miller, after having reported upon a question which I daresay he fully understood, ventures upon this opinion:—"A scheme has been proposed for "collecting and abstracting water from the sources "of the rivers Verniew, Banw, and other tributaries "of the Severn for the purpose of supplying London. "If this scheme (which I consider a wild one) should "ever be carried into effect, it would be even more "destructive than the loss that has been caused by "the mill weirs, which are capable of being remedied, "whilst the total abstraction of water from these pure "mountain streams, which include about 150 miles of "the finest spawning grounds, would be utter ruin to "the fisheries. I hope, therefore, your board will zealously watch the movements of the promoters of the "scheme." Now a gentleman who is supposed to have read my report, and who comes to the conclusion that there is to be a total abstraction of water, when the stream will be improved as far as its dry weather quantity goes, is not very competent to form an opinion upon the undertaking itself, and when he says that an interference with 150 miles out of 650 miles would be utter ruin to the fisheries I think that his conclusion is equally untenable. I merely point that out to show that the opinion of this gentleman cannot be relied upon on a matter which he is apparently not capable of mastering.

134. Having detailed to us the quantity of water, and the method by which you propose to collect and store the water, it will now be the proper time to give us the manner in which you propose to convey it to London?—I will do so; but I must remind you that I have omitted to refer to two important questions before we leave the collection. The water is in itself probably as pure a body of water as can be collected anywhere. There is a greater absence of peat upon these hills than is commonly the case on hills in similar districts, and the streams generally run remarkably bright, not as bright as in a limestone district in wet weather, but in dry and cold weather they run as bright as from a limestone district and a coa measure district. When they are collected in such very large bodies as is proposed here it is not necessary to adopt any system whatever for clarification or purification. Any colour with which the streams may occasionally be charged is discharged on exposure in these large reservoirs, or by subsidence. Loch Katrine, which is probably as fine a body of pure water as any in the world, and is almost absolutely colourless, is fed by mountain streams, which in summer and in autumn are as brown as porter. I have never seen a darker stream, even from a bog in Ireland, than the river Strowan, which flows into Loch Katrine, and is one of the principal contributors to it on the northern side of the lake, but all the colour is discharged by exposure to the atmosphere in so large a surface, namely 3,000 acres. That is also the case in the Manchester waterworks and in all the other waterworks where the water is collected in a large body, however coloured it is in the first instance its impurities become removed by time and exposure. But here, as in the Manchester waterworks, if necessary, a principle of separation may be most conveniently adopted, by which every stream, no matter how small or how large, is made to separate itself, pure water going in one direction and turbid water in another. The streams, as long as the weather is cold, or as long as they are unaffected by a heavy fall of rain, even in a very wet and in a very discoloured district, are always at that time pure stream water, and perfectly colourless, and they only become coloured on the occurrence of heavy rain which disturbs the state of things and brings down foreign matter, either colouring matter from the peat, or colouring matter from the clay soil, or the soil which has been disturbed by water running over. Therefore, you only have to take advantage of those two circumstances, namely, that the small stream or the stream unaffected by rain is pure, and that the large stream is or may be impure, and you can easily arrange the separation of every stream. I can readily show you how that is done. Suppose a weir to be built across a stream, which is a tolerably large one, with a subterranean passage underneath the top of the weir, and in front of the top of the weir a little slot, which allows communication with the subterranean passage, a small stream drops through that slot into the passage beneath. As soon as the stream is swollen by heavy rain, and the velocity is great, it jumps that slot and goes down the other way, it goes down the weir.

Therefore, the pure water which drops through the slot may be conveyed away by a side channel into a reservoir for pure water, or direct to the place where it is to be supplied, and the turbid water going down the weir, and so down the river course, may be stored in reservoirs set apart for that purpose, where it may settle and bleach, and ultimately become pure enough.

135. (*Sir J. Thwaites.*) Will not that arrangement carry the water in a mixed condition?—No, it separates it perfectly. When the water is pure it will be received in the subterranean channel. The slot is so arranged that a small stream just drops through it and is conveyed away by a subterranean channel, but the moment it is swollen, and when it is turbid, it jumps that slot.

136. (*Col. Harness.*) If I understand you rightly you would only receive the pure waters which come down in seasons of quiet and would not save the flood waters?—We should save both. This is a plan of the Manchester waterworks (*producing the same*). This upper reservoir is a reservoir for flood and turbid water; the second reservoir, next below, is also a reservoir for turbid water; the next below that is a reservoir for pure water, and then all the reservoirs from there to Manchester are reservoirs for pure water. The turbid water flows into the two upper reservoirs (*pointing out the same*); the pure water is carried round them, and is either taken direct to Manchester, or if it is more than sufficient for Manchester it is discharged into other reservoirs. The turbid water is stored for compensation for mills, and after it is sufficiently clarified it is also taken to Manchester. I will now show you the actual thing in operation. This photograph will show you one of the larger weirs constructed upon the Manchester waterworks (*producing a photograph and explaining the same to the Commissioners*). That arrangement wants no attention, it never goes wrong, and it acts perfectly. It was originally designed with the view of having a little flap in front of the slot, which, as the stream diminished should be also diminished, but in practice we find that that is not necessary. The slot is well proportioned for its purpose, it receives all the pure water, and all the turbid water goes over. Therefore here, in the scheme before you, you can always separate the water in that way if necessary (which I do not think would be necessary), and you can devote some reservoirs to the storage of pure water and some to the storage of turbid water. Then, again, we find that where water is stored in large quantity derived from this geological formation it requires no filtration. There is none in Manchester, there is none in Halifax, there is none in Glasgow, there is none in Blackburn, and there is none in almost all the large waterworks which I have constructed, but we strain the water through copper gauze in order to prevent the admission of any extraneous matter, and those gauze strainers are so arranged one before another that they can be taken out and cleaned from time to time, and everything can be prevented from entering the pipes. Then the service reservoirs, in order to prevent vegetation, must be at least 15 feet deep if uncovered; at less than that depth vegetation takes place, and upon the decay of vegetation animalculæ occur, which must be prevented from entering. In the Manchester waterworks our service reservoirs are from 18 to 20 feet deep, and we never see a particle of vegetation, and they have now been at work for about 14 or 15 years. That water is derived from the millstone grit. In Glasgow, in the same way, our service reservoir is deep, and we have not a particle of vegetation, and where the current of the river is tolerably deep no vegetation takes place. I have a drawing which will show you the arrangement for straining the water before it enters the pipes. This is one of the service reservoirs at Manchester, it is 18 feet deep at one end, and 20 feet at the other (*the witness explained the same to the Commissioners*). The water is brought from the hills and carried up the centre embankment of duplicate reservoirs to the extremity of the service reservoirs, where it is admitted to each reservoir, and then it circulates through the whole of the service reservoirs, and is passed through strainers to the pipes which carry the water to Manchester. In front of the pipes there is a basin which is covered over, it being a sort of tank, and there are vertical pillars in which the strainers are fixed, through which the water has to pass. The straining frames are divided into small compartments, which can be renewed from time to time, and as one frame is taken out another is put in behind it. They are taken away and washed, and are brought back again, and it answers the purpose perfectly. The water is delivered wholly free from floating matter. The same arrangement is carried out in Glasgow. As to the size of the wire gauze of the strainers at Manchester, there are 60 strands to the inch, but that is rather finer than is necessary. I believe that about 40 strands to the inch would practically be quite sufficient.

137. (*Mr. Prestwich.*) I see that at page 30 of your pamphlet you give a rough analysis of the waters flowing down the different streams, separating the organic impurities from the inorganic impurities. The organic impurity in those streams appears to me to be very large in proportion to the inorganic impurity. Can you account for that in any way?—That is not a large amount, practically both the Loch Katrine water and the Manchester water have very nearly one grain of organic impurity. The river Vyrnwy only has three-fourths of a grain, and the river Severn at Caer-Sws has 1·44, and there is 1·96 grain of organic impurity at Llanidloes Bridge; but that is taken at Llanidloes Bridge where there are some lead works, and there is a stream there which I reject. The 1·96 includes what was coming down from lead works worked in that valley, and which I have consequently rejected. There are two or three mills there, and also the sewage of Llanidloes, and therefore that 1·96 ought not to be taken as a test. The others would vary from 1·44 down to three-quarters of a grain, the mean perhaps being one grain. Bala lake has $1\frac{1}{4}$ grain of organic impurity. Bala lake may be said to be a fair sample of the water to be collected, because that is the stored water of the district. But then Bala lake has been formed by the detritus which has been brought down by another river, filling the valley and making a sort of gravel bed, over which the water cannot escape. A very great amount of detritus is brought down there, and has filled that valley with gravel, and that forms Bala lake; and therefore at the outlet of Bala lake there is shallow water, which may account for the great amount of organic impurity.

138. It is much greater than that of the Loch Katrine water; it is double the amount?—Yes, but there is no reason for that.

139. At what period of the year was the water for your analysis collected?—I am not quite sure, but I am told that it was in May. The Manchester water supply has only two-thirds of a degree of organic impurity, and the Loch Katrine water has about the same; and there is no reason whatever why the organic impurity in these waters when collected in reservoirs should be larger than in either of those cases.

140. (*Col. Harness.*) Is any measurement taken by which you determine the quantity of water consumed in Glasgow and in Manchester?—In Glasgow the water is conveyed from Loch Katrine by a covered conduit; it is passed over a gauge weir as it enters the service reservoir. The actual capacity of that reservoir is known to every inch in depth, and the quantity entering and the quantity either increasing or diminishing in the reservoir is daily registered, so that we can ascertain the daily consumption in that way. The measurement is determined by the water flowing into the reservoir, and the quantity contained at any time in the reservoir.

141. Is the reservoir perfectly tight?—Yes. This photograph shows the service reservoir of the Glasgow waterworks (*producing the same*) and the gauge over which the water is gauged is shown. It then goes into the smaller reservoir and it is then gauged again. That shows the actual amount of water entering; then

J. F. Bateman, Esq.

7 Feb. 1867.

if the reservoir lowers in the course of the day it is taken.

142. It is still subject to evaporation?—Yes, but that is not very much; it is a trifle more than one-tenth of an inch in the hottest day in summer, when the weather is most suitable for the absorption of moisture. In Manchester the same process is followed; the water is admitted into a basin where it is gauged and passed into the service reservoirs, and the quantity contained in the service reservoirs is known, so that there can be no question as to that matter.

143. (*Mr. Harrison.*) Were these waters analysed by anyone but Dr. Thomson, who is now dead?—Not for me. Dr. Thomson is, I think, the only person who analysed the waters. We had in other places an enormous number of analyses made.

144. From these Welsh mountains?—No, not in the Welsh mountains, but in mountains of a similar geological formation. The waters are so similar when they come from the same geological formation, and from the primary rocks especially, that the analysis of the highland loch water may be taken to be the analysis of the English lake water or of the Welsh lake water.

145. (*Sir J. Thwaites.*) Has not Dr. Odling made some analyses?—It is very probable that other chemists have made analyses. In order to show how almost identical these waters are I have before me some analyses by various persons, and particularly by Dr. Allen Miller, and by Mr. Penny and Mr. Redwood. The water supplied to Whitehaven, that being from an English lake, contains of organic matter ·46 grains, and of fixed salts 1·60 grains, being a total of 2·06 grains. The Loch Katrine water contains a total of two grains, the organic matter is ·52 as against ·46, and the fixed salts are 1·48 as against 1·60. You will find that the Bola lake contains 2·08 of total impurity, of which the organic impurity appears to be greater than in the other cases, but there is no reason why it should be so.

146. (*Chairman.*) Will you state the mode in which you propose to convey the water to London?—In conveying the water from the hills to London I do not know that I can better describe the mode in which the water is to be conveyed than by giving you a description of the manner in which it is conveyed from Loch Katrine. The first 11 miles or thereabouts of the district on the Glasgow side of Loch Katrine consist of clay slates and mica slates, which are almost impervious to water, and of very great hardness for the most part, and if I have any credit at all for executing the Loch Katrine waterworks it arises from the geological knowledge which I possessed. I saw that everybody who had gone to Loch Katrine before me had missed his way in proposing to make conduits upon the surface of the ground. There was no clay in that part of the country and no means of transporting materials, but they had rocks which, if they could once bore a hole through, would be as lasting as the hills themselves, and perfectly water-tight. I therefore saw that we might sink any number of shafts or drive tunnels without the danger of being troubled with water, which is the great element of difficulty and cost in the construction of tunnels. I accordingly determined to drive tunnels for the greater part through those geological measures, driving from valley to valley, and never having any long tunnels if I could avoid it, but having short tunnels from valley to valley, so that you might come out in the valley and discharge your materials from these various outlets. Upon that system I made the works, and I am quite sure that it was the best, the cheapest, and the most durable method; consequently we had, I think, 70 different tunnels of comparatively short lengths. Here is a section of the Glasgow waterworks. We commence with Loch Katrine, and we have first of all boldly to face a hill which rises above the level of the lake at the point where we cross it, about 500 to 600 feet. We then get out into another valley, and then we have a series of short tunnels which have been driven. All these darker portions of colour are actual tunnelling, and all the lighter portions are cut open.

147. (*Sir J. Thwaites.*) Through what material is this?—Through mica slate. Then we get into a desperately hard country, but they are short tunnels. All the darker parts are tunnels, and all the light parts are "cut and cover," as it is technically called, till we get to a valley where we have syphon pipes across. For the first six or seven miles we go along the rough sides of the mountains till we get upon the summit of a ridge which separates one valley from another, and then we have to carry the water across by wrought-iron aqueducts till we get to a deep valley, which we cross by syphon pipes rising to the other side; and then we proceed with the same description of tunnels till we get to the old red sandstone, where I was afraid of water, and there I avoided tunnelling as much as I could, because I was afraid that I should be drowned out with water. There are cast-iron pipes across the vallies with a fall of five feet in a mile. Through all the upper part through the slate formation there is very little more to do than to tunnel, making a hole of the necessary size. Wherever the rock was sufficiently hard to endure exposure, it was merely shaped out to the proper size of tunnel. Wherever the material was soft and required lining, it was lined, but there was very little lining till we got out of the clay-slate formation.

148. (*Sir B. Phillips.*) What was it lined with?—With brick or stones, as the material was best at hand. The fall is 10 inches in a mile, and the size of the conduit is 8 feet high by 8 feet wide (it is not circular), and it is capable of conveying at 6 feet 6 inches in depth 50,000,000 gallons of water per day, the quantity which we are entitled to take from Loch Katrine. When we got to the valleys we crossed them by syphon pipes, allowing 5 feet fall in a mile. I can show you drawings of the aqueducts. This (*producing a photograph*) is one of the aqueducts.

149. (*Sir J. Thwaites.*) There are stone piers?—Yes. Here is another photograph (*producing the same*); this shews an aqueduct in course of construction. Approaching the aqueducts which are coloured dark red, we built the aqueduct of a stone embankment, and upon that we put a cast-iron trough, and then we have a wrought iron tube a little lower than the trough for the purpose of securing that the trough shall always be wholly immersed in water, so that there shall be no unequal contraction by a hot sun on a summer's day.

150. What is the object of covering this portion (*pointing to the photograph*)?—Because it is the strongest form, and also to prevent the sheep from falling in, and the snow drifts.

151. (*Sir B. Phillips.*) What is the distance from Loch Katrine to Glasgow?—About 35 miles. The cast-iron troughs are not covered. This (*producing another photograph*) is a drawing showing the work in course of construction of this bridge (*pointing out the same*).

152. (*Sir J. Thwaites.*) How many pipes have you?—One four-feet pipe, with 5 feet fall in a mile, conveys rather more than 20,000,000 gallons in a day. They have used our 20,000,000 gallons, and we are now putting down a second pipe conveying 20,000,000 gallons more.

153. Your tunnel through the rock is for the full quantity?—Yes, and the wrought-iron troughs are for the full quantity. The cast-iron troughs were made 4 feet 6 inches high, and by increasing the depth they will take the full quantity.

154. Supposing that a pipe wants repair, what provision have you?—There is ample provision for that and for all contingencies. This is another photograph (*producing the same.*) I believe that all the people in that part of the country thought that I was utterly mad in carrying a line of conduit there, and I have frequently stood upon this summit, and did not wonder that the people thought so; it is about the roughest country in appearance to pass through which anybody can conceive. That photograph was taken during the working. Almost turning your back

upon it, and looking forward towards Glasgow, you look over a totally different character of country from the different geological formation, one being over the clay slates and the other over the old red sandstone. It is a desolate district of 5 or 6 miles. After passing through that old red sandstone formation, we come to a long depression of something like 2½ miles across a river, and across a railway, and that is all done by syphon pipes. The pipes have to bear that amount of pressure. In one or two cases we had to cross over railways, and we adopted that plan of putting the pipes upon pillars.

155. In these cases do you thicken your pipes in order to resist the pressure?—It required no increased thickness.

156. (*Col. Harness.*) Have you used a single line of pipes?—We had a single line of pipes in the first instance, and we are now putting a second line of pipes. Then we have a large service reservoir near Glasgow, which is sufficient for supplying the city for about three weeks without any assistance from the hills.

157. (*Sir B. Phillips.*) Are these works inspected from time to time in any way?—Engineers are constantly upon the spot. These works may be literally said to have cost nothing since they were constructed, except the cost of inspection and looking after them. They are very successful. There are various other aqueducts. In a stone country we build stone aqueducts. I may state that in driving tunnels through this formation it is very slow work. In one part for a considerable distance we only accomplished 3½ yards in a month.

158. (*Mr. Prestwich.*) What is the elevation of the reservoir?—About 313 feet above the Clyde at Glasgow. Loch Katrine is 363 feet above the Clyde at Glasgow, and we therefore lose 50 feet in conveying the water. Tunnelling, where you have short tunnels and where you can bring out the work to daylight at short intervals, is perhaps the cheapest and the best and quickest way of getting through a country of this sort. Where you have long tunnels, and at a great depth below the surface of the ground, you get into great difficulties. The Loch Katrine tunnel, which is 2,325 yards in length, although not the longest, was at the greatest depth below the surface of the ground, and we had five shafts at about 450 to 500 feet in depth. Four of those shafts varied from about 110 to 120 yards in distance apart. We had altogether 12 shafts and two loose ends, which made 26 faces at which we could work, there being two faces at each shaft. The work was commenced in the spring of 1856. The work was completed, and the water passed through, it being opened by the Queen in October 1859, the time occupied being about 3½ years from first to last. But in order to complete the work within that time, we had to sink a great number of shafts. The deeper shafts, those of about 450 feet in depth, took us upon the average from 20 to 22 months to sink, and then we occupied about three or four months in driving, but it was all driven through in 2½ years. But then we had to shape and line the tunnel, which took a great deal of time. When you get into great depths you can hardly get through a work of this sort in any reasonable time, because the shafts take you a long time to sink. Here you have an instance where, in order to complete the work within the period of 3½ years, and where the tunnel in this formation was only 450 feet, as far as the shafts were concerned, below the surface of the ground, you had to sink a shaft at every 200 yards, the deepest and most costly shafts being within 110 to 120 yards from each other, and they took about 22 months to complete before you could commence the tunnel itself. The Mugdock tunnel was through basalt, which is not so difficult by any means to drive through as the Mica slate. There the shafts were fewer in number, and not so deep, but that tunnel took us a longer time to make, in consequence of the less number of shafts than the Loch Katrine tunnel itself, but they were both completed at about the same time.

I have, therefore, in laying out a conduit from the Welsh hills, taken advantage of all the experience and knowledge which I have acquired in the construction of the Loch Katrine works, as well as other works, although that is the largest example, and I consequently have endeavoured as long as I was in the hills to adopt the same system, and till you get into the open flat country there is no difficulty. I do not consider a short hill any difficulty. The conduit passes along the slopes of the hills and spurs of the mountains, excepting one or two ridges which it must cross. There is the Wenlock range. From the reservoirs themselves upon the two branch conduits to their point of junction the work is of a very similar character to that of the Loch Katrine works. We go upon the slopes of the hills, tunnelling through the great headlands, and always avoiding being much above the surface of the ground at any point, so as always to have the watercourse in secure ground, and where we cannot avoid it we cross the valley. For instance, above Welshpool on the road to the point of junction near Marten Mere, we have to cross the river Severn proper with a syphon pipe, and from the Trefeglwys reservoir we have to cross the Severn. After we have crossed the Severn we adopt the same principle as in the case of the Glasgow Waterworks. I have not prepared an accurate section the whole way, but the whole country has been walked over, and the line determined. There are no Ordnance maps in that part of the world, showing the level, but there are a great number of railways and canals and so on, from which the levels at certain points may be fixed, and by the aid of those, and with the Aneroid barometer, and walking over the whole country, we have determined the line of route to be taken, and I am satisfied that within a very trifle the route marked there, until we get to Bridgnorth, is as nearly as possible the line which upon a more accurate survey would be taken, and at all events we have allowed sufficient for any possible deviation. When we get to Bridgnorth we have to pass the river Severn at an elevation of something like 300 feet above it, and we then get upon almost the summit of the country, and we get into the swelling features of the centre of England, where it is much more difficult to find our way, and there probably we may find upon survey, that here and there considerable improvements might be made upon the line which has been adopted. After passing Bridgnorth we go a little below the summit of the country till we come to the river Avon valley which we cross below Warwick, by a deep depression, and then we get as nearly as possible to the summit level of the drainage of the Thames basin. We cross it several times, and that is nearly the summit of the country in the centre of England, and there are great swelling features so that it is difficult to determine the exact way, but as nearly as we can tell, this is the line to be taken. A conduit of this nature is not like a railway or a canal. A railway may be made to go up any hill, or down any valley, at an inclination, and the same with a canal by locks; but a conduit for conveying water from one given point to another by gravitation, must have its regular inclination of so much a mile, and it must follow the contour of the country. If it comes to a hill which it cannot get over, it must go through it, and if it comes to a valley where the levels do not suit, you must either bridge it or it must go by syphon pipes. It is therefore fortunate if you can get a line which will avoid difficulties, especially the difficulty of going through a very populous country, which it is desirable that a conduit of this sort should not do, and the difficulty of going over a coal field. It so happens that in this line you absolutely avoid everything of this kind. You have about a mile of coal field, but the coal is not worked; that is the whole which you have between the reservoirs and London, and that occurs just to the west of Bridgnorth. You go through no town at all. Newtown in the Valley is the only town which you may be said to touch. You go near towns, but you avoid the towns themselves. At Bridgnorth you go about a mile above. You go very close to

J. F. Bateman, Esq.

7 Feb. 1867.

J. F. Bateman, Esq.

7 Feb. 1867.

Newtown. At Montgomery you go a mile away. Between Montgomery and Bridgnorth it is a desolate country; from there you do not come near any town till you get to Bromsgrove, and there you get to the north of the salt district. You are to the south of the midland coal field, and therefore you are on perfectly sound ground. From there you go two or three miles below Warwick, and get into the open country, and you do not go near another town till you get to Banbury, which you are not very far off, and till you get to Berkhampstead, and on the line which the London and North-western Railway traverses, to near Stanmore. I can show you a section as nearly as we can make it of the portion from Bridgnorth forwards. I can in the same way prepare a section from Bridgnorth to London.

I may say that I selected this district with a perfect knowledge of what every other part of the country could do. I was aware of the vast quantity of water, and about which there can be no kind of question, in the Lake district, and the elevation of the Lakes; and I knew that those Lakes from which water could be obtained were not higher than the sites of reservoirs, which could be formed just as large as Lakes, and better than Lakes, because you could make them hold more water in the same area in the Welsh hills. Therefore, not only with reference to distance, but with reference to inclination, it was most important to get the water which you wanted at the nearest point. The backbone of England is not only now largely drawn upon by a great many large towns on both sides, in Yorkshire and Lancashire, but it neither possesses the facility for constructing reservoirs, nor the vast amount of rainfall, nor the large area of drainage which for the metropolis is necessary, nor ought it to be tapped because it is, in fact, the natural resource of all the manufacturing towns in Lancashire and Yorkshire and Cheshire, and therefore the Derbyshire hills and the Yorkshire hills were out of the question. The only two districts from which water could be derived were the English lakes and the Welsh hills, without interfering with what might be considered in a national point of view the property of other districts. But the English lakes, at no greater elevation than the Welsh hills, were at twice the distance or nearly so. A direct line from London to the reservoirs in Wales is 167 miles. A straight line from London to Ulleswater is 212 miles, being a difference of 45 miles in a straight line. The distance to be traversed from London to the Welsh reservoirs is 183 miles; the distance to be traversed from London to Ulleswater would exceed 300 miles. It is 308 miles by a line I have sketched out, but it may be shortened about 19 miles by very heavy tunnelling, in a difficult part of the country, so that that would make it 289 miles, which may be called in round numbers about 300 miles. You therefore have a difference of 120 or 130 miles between the one scheme and the other; the elevation of the reservoirs in Wales and the elevation of Ulleswater being nearly the same, the discharge pipe of the Welsh reservoirs being 450 feet above Ordnance datum, and the level of Ulleswater being 476 feet above Ordnance datum, from which, if you deduct something like 16 feet, the depth to which you must draw the water from Ulleswater in order to make it a reservoir at all, it will give you 460 feet. Therefore, at 300 miles off you have a starting point of 460 feet, against a starting point of 450 feet at 183 miles off. The result is, that after allowing for the loss of fall which must accrue wherever you have to cross a river or a valley by syphon pipes, where you have to allow, in order to avoid expense, five feet of fall in a mile, you can in the one case get an available fall for your conduit of about an average of from 10 inches to a foot in a mile, delivering the water at 250 feet above Ordnance datum at your service reservoirs 10 miles from London; and in the other case, after allowing for syphons, you can only get an available fall for the whole of your conduit of about 7 inches in a mile, and consequently, to convey the same quantity of water, inasmuch as velocity and power of conveyance depend upon declivity, you must have a larger conduit from Ulleswater than you must have from Wales, the result being that in addition to the greater length you must have for the whole of the distance a more costly aqueduct to convey the water. I merely mention this matter because a consideration of all these circumstances (and I gave the whole subject full consideration) determined me in going to the Welsh hills. I saw that there you could get everything nearer, and at an elevation which would enable you to make the works cheaper than in any other part of the kingdom.

159. (*Sir J. Thwaites.*) What is the increase of capacity as between 10 inches and 7 inches?—A given conduit which from Wales would convey 300,000,000 gallons a day, would only convey 240,000,000 gallons from Ulleswater.

159*a*. (*Col. Harness.*) I observe that your reasoning is based entirely upon Ulleswater, and not upon the possibility of making artificial reservoirs in that district, as you propose in Wales?—You would not gain anything by artificial reservoirs because Ulleswater is a high lake. There is another lake higher still, namely Haweswater, and there are points where you can make artificial reservoirs. You must make your reservoirs at the bottoms of the valleys at elevations high enough, and you would get so high up the mountains in order to get a fall to London that you could not make the reservoirs in the valleys. Quite apart from that, the distance itself is so great that it would not be worth while to go there for the water. You cannot get reservoirs of sufficient capacity and commanding a sufficient area in the Lake district to give you the same inclination per mile.

160. You say that from your examination of the country?—From the physical condition of the country you cannot find valleys in the Lake district high enough to enable you to make reservoirs by which you could bring the water at the same inclination per mile, the distance being so much greater.

161. (*Sir J. Thwaites.*) It is not a question of distance, because you have the reservoirs already formed and at an equal elevation as that which you propose?—Yes, and at nearly twice the distance. I admit that there is plenty of water in the Lakes, and plenty of reservoir space, both that which is natural and that which may be constructed artificially; but then the distance for which the water has to be conveyed is in my opinion entirely prohibitory.

162. (*Col. Harness.*) The distance is half as far again?—The distance is as 170 to 310 in round numbers.

163. You have a working head of 200 feet?—We have not a working head.

164. You have a difference of level between your reservoir in Wales and the point at which you deliver in London of somewhere about 200 feet?—Yes.

165. If the distance is half as much again another 100 feet would make the position the same in the lakes as in Wales?—Yes.

166. What have you to say against that, because you have only reasoned upon Ulleswater?—There is no other lake which is high enough.

167. Is there no reservoir 100 feet higher than Ulleswater?—Yes, Haweswater would be higher; and you could make reservoirs higher, but I believe that you could not make reservoirs of sufficient capacity at the proper elevation.

168. You have not examined the matter with that view?—No; but I can very easily do it because the whole of that country is contoured, and we have the ordnance map, but knowing the whole district very well, having made large reservoirs there, I do not believe that it could be done; however, I do not mean to say that it cannot be done. My estimate for the cost of conveying the water is on the average 35,000*l*. a mile, and supposing that the works are no more difficult and no larger in going through the Lake district than in going through the Welsh district, but that you have about 130 miles more, you have

130 times 35,000*l.*, which will be 4,500,000*l.* or 5,000,000*l.*

169. How have you arrived at that 35,000*l.*; is it by comparison of what similar works have cost?—It is by my actual estimate of the work to be made.

170. (*Mr. Harrison.*) Upon what quantity of water is your 35,000*l.* per mile?—That is taking 220,000,000 gallons a day, but there would be very little difference in the cost, by a little change in the design, between making a conduit which would convey 220,000,000 gallons and one which would convey 300,000,000 gallons. At the end of the pamphlet before you you will find the designs for conveying 220,000,000 gallons a day with a fall of 14 inches in a mile in a covered conduit, and about the same quantity with a fall of 6 inches in a mile where it is open. Where you go through a perfectly open agricultural country you may make the conduit open; there is rather an advantage to the water than otherwise in its being exposed. Where you go through a populous district, or through a thickly wooded country, or upon the slopes of mountains where snow is liable to drift, and possibly to choke you, it is desirable to cover the conduit. Therefore I have assumed that half of the whole length should be covered and half of it open. This (*producing a drawing*) is a slight modification, and a very slight one, of the sketch which appears at the end of my pamphlet. Taking the open part first, that which is coloured pink, is the necessary work for conveying 220,000,000 gallons of water in 24 hours. The addition of these little purple bits, and the extra depth represented by the blue colour would enable that conduit to convey 300,000,000 gallons a day. In the covered portion, by adding 18 inches to the width of that which is shown in the sketch, and by giving a quicker invert a greater quantity of water can be conveyed. At 10 feet deep the conduit will convey 220,000,000 gallons or thereabouts, and by adding 2 feet in depth it will convey 300,000,000 gallons of water a day.

171. There are 6 inches fall to a mile in the one case, and 14 inches in the other?—Yes. With the fall which could be allowed from Ulleswater those conduits would convey up to the top of the blue line 240,000,000 gallons as against 300,000,000 gallons, taking Ulleswater as 460 feet, and the Welsh reservoirs as 450 feet, I get an available fall of 10 inches, taking the mean. From Ulleswater the available fall would be about $7\frac{1}{3}$ inches, which would give 10 inches for the covered part and about 5 inches for the open watercourse; and with those different declivities the same conduit would convey four-fifths of that quantity of water.

172. Is that assuming that the service reservoirs would be at the same height?—No; that is assuming that the service reservoirs from Ulleswater would be about 200 feet above the level of the sea, and the service reservoirs from the Welsh district 250 feet. Mr. Harrison will see that the strength of the work upon that section is very considerable, and that where we go through ground which is in itself water-tight, or is in itself hard enough, nothing like that quantity of work would be required. Those drawings are prepared for a difficult country, where the work requires being made water-tight, and very strong work to prevent injury.

173. This drawing does not show the depth of cutting necessary to arrive at that result?—No; but we are obliged to take an average, and I have taken 15 feet of cutting the whole way through, and upon that I have calculated the quantity of excavation. I put 2*s.* per cubic yard for the excavation at 15 feet deep.

174. Do you think that you could calculate exactly upon getting a line through that district with not more than an average of 15 feet cutting?—Yes; except where you tunnel, and then tunnelling is as cheap as anything else.

175. I suppose that in that case you take it from the top of the work?—Yes; you would generally have a little hillock over the covered part. Many times you would have not more than 10 feet, and sometimes 20 feet. I have allowed 60 cube yards of cutting on the average of the whole. For the covered aqueduct I have allowed $7\frac{1}{2}$ yards of brickwork at 20*s.* a cube yard. For ashlar skew-backs I have allowed 2*s.* a cube foot, concrete 10*s.* a cube yard, and excavating 2*s.* a cube yard. Then I have sundries. Then I have the land in addition, and I have 15 per cent. upon all this work. I allow 1,500*l.* a mile where the ground is covered for crossing drains or small streams, either under or over. Then in the open conduit I have the same prices for brickwork, and I have 3,000*l.* a mile for fencing, and for culverts over or under, and for bridges. Now all that I have to do in the bridges is to introduce a little bit of covered waterway instead of open, and the difference is only about 3*l.* a yard between the covered and the open waterway. Then I have a further sum of about 120,000*l.* for any difficult works which may occur, anything beyond what is covered by this estimate, which I consider a large one, because I have the experience of Glasgow, where I know pretty well what the average cutting was. Our general plan was to keep ourselves rather more than half in cutting, and about half filling over, so that we might have the lower half in the solid, and the material which we excavated would be heaped up over the work and form a waling as it were all along. We merely had to take care that the drainage of the country was not interfered with by that means. Therefore we got half the depth of our work, and there the material was heaped on to the top.

176. Will you give the length of tunnelling on your Glasgow works?—The length of tunnelling on our Glasgow works was 13 miles out of 27, the distance from Loch Katrine to the Mugdock reservoir; that is direct tunnelling.

177. What proportion was carried by pipes?—For 8 miles by road from the service reservoir to Glasgow there are two lines of pipe.

178. Of course the remainder will be open work?—There is no open work at Glasgow; the whole was tunnelling or cut and cover. Of the 26 miles which lie between Loch Katrine and the service reservoir 13 miles are tunnelling, $3\frac{3}{4}$ miles are iron piping, and the remainder, where the ground has been cut open, is an arched aqueduct of 8 feet in diameter, having the same inclination as the tunnels.

179. Can you give me the total cost?—The total cost of works, including reservoirs and piping in the city of Glasgow, and land and houses, and everything else so far as engineering cost went, was about 700,000*l.*, the distance being 35 miles. The total cost, everything included, was nearly 900,000*l.* The most costly tunnel which we made, including everything, was about 15*l.* a lineal yard, including the shafts. I believe the cost of the tunnel was about 12*l.* a yard; including the shafts and every expense it was about 15*l.* a yard.

180. (*Sir J. Thwaites.*) The 35,000*l.* a mile does not include the cost of the reservoirs?—No.

181. Neither in Wales nor in London?—No; that is the mere cost of the aqueduct itself, the construction of the work and the land which it will occupy; it does not include reservoirs in Wales nor the service reservoirs in London, nor the piping from the service reservoirs to join the other piping.

182. (*Mr. Harrison.*) As I understand you the total cost of the engineering works in the case of the Glasgow waterworks was about 700,000*l.*?—It was 712,000*l.*; that included the whole of the piping in the city of Glasgow.

183. Including the whole of the works the land and every contingent expense, it was 900,000*l.*?—I think that what I have stated did not include the land. The cost of the engineering works in the service reservoir at Mugdock, the aqueduct, and two lines of pipes to Glasgow was 712,000*l.*

184. What was the additional expense to make the total 900,000*l.*?—It was for land and parliamentary contests, and engineering superintendence, and interest on money during the construction of the works, and everything of that sort.

J. F. Bateman, Esq.

7 Feb. 1867.

185. Did you calculate that the actual distance occupied about 35 miles to Glasgow?—Yes, in round numbers.

186. That, everything included, was under the cost of 35,000*l.* a mile which you are now taking?—Yes, but the one is for 50.000,000 gallons, and the other for 220,000,000 gallons or more.

187. Do you recollect what you paid for the old works at Glasgow?—We purchased two waterworks, together I think they were between 500,000*l.* and 600,000*l.*

188. (*Chairman.*) That was for all the waterworks in Glasgow?—Yes.

189. (*Mr. Harrison.*) What is the rating in Glasgow?—The rates actually levied in Glasgow are 1*s.* in the pound on the rateable value for the domestic supply, and 1*d.* for the public rate; there are two rates, one a domestic rate for the supply of houses, which take the water for a domestic purpose; and in addition to that, upon those houses and upon all other property, with the exception of some modified charge for railways and other things, there is a rate of 1*d.* in the pound, which makes the total charge upon houses 1*s.* 1*d.*

190. What was the rate before the new works were introduced?—The rate was the same, or rather more, it was 1*s.* in the pound by the old companies, and it is only 1*s.* in the pound now. On page 20 of my pamphlet you will find the following statement: "Shortly "after the completion of the Loch Katrine works, "when the full amount of interest on capital came to "be paid, and before the expansion of the supply for "trading purposes had had time to develope, the "domestic rate in Glasgow rose to 1*s.* 4*d.* in the pound "on the north side of the river, which in addition to "the public rate was cheerfully and thankfully paid." It has fallen now to 1*s.* for the domestic rate, and a penny for the public rate. Then in Manchester the actual rates paid are 9*d.* in the pound for the domestic rate, and 3*d.* in the pound for the public rate.

191. (*Sir J. Thwaites.*) That is a compulsory rate?—It is a compulsory rate in both cases.

192. That is to say, that supposing rateable property does not receive the water, it is obliged to pay?—Yes, everybody is obliged to pay; they must have water, and if they do not take the water in the regular way they must steal it. All houses must pay the rate, it is compulsory upon everybody to pay the water rate.

193. Take a warehouse, for instance?—A warehouse must pay 1*d.* in the pound in Glasgow and 3*d.* in the pound in Manchester. If you take it in round numbers, some years ago the rateable value of property, both in Glasgow and in Manchester, was 1,200,000*l.* Of that sum, in both cases, about 600,000*l.* was the rateable value of dwelling houses, and upon the 600,000*l.* in Glasgow you levy 1*s.* in the pound, and in Manchester 9*d.* in the pound. Upon the 1,200,000*l.* in each case you levy a 1*d.* in the pound in Glasgow and 3*d.* in the pound in Manchester.

194. (*Mr. Harrison.*) Was it the fact that before these works were completed, and before the inhabitants were charged with any interest upon the works, they had to pay 1*s.* in the pound in Glasgow?—Yes.

195. And you have expended 900,000*l.* without their paying any more than they paid before?—Yes, except for the first two or three years after the works were introduced, and then the rate remained the same as before. They left a little deficit, and they rose the rate to 1*s.* 4*d.*, and they dropped it to 1*s.* 3*d.*, and then they dropped it down to 1*s.*, the same as it is now. Therefore the rate now is no more than it was before they expended in round numbers a million of money, and from this time it will become less.

196. (*Sir B. Phillips.*) I suppose that as the debt becomes liquidated the rate will decrease?—Yes, the liquidation is very slow, but in time the whole thing will be free, except the cost of maintenance.

197. (*Mr. Harrison.*) In this case you have generally based your estimate upon the experience which you obtained in the execution of your Glasgow waterworks?—At Glasgow and Manchester, and every other place.

198. (*Sir J. Thwaites.*) Can you tell us the rate of interest at which you raised your money in Glasgow?—I do not quite know that, but it was between four and five per cent.

199. They have no Government guarantee?—No; but there are compulsory rates upon the whole of the property in the city.

200. (*Sir B. Phillips.*) There is power I suppose under the Act of Parliament to raise the money and to levy a rate?—Yes; it is not only a compulsory rate, but as far as the domestic rate in Glasgow goes it is unlimited; it is limited to 2*d.* in the pound I think for what is called the property rate in Glasgow, and it is unlimited as far as the domestic rate is concerned. In Manchester both rates are unlimited as well as compulsory.

201. Do you mean by "unlimited" that there is no defined sum under the Act of Parliament?—Whatever money they want to pay the interest of the money borrowed, if it is 5*s.* in the pound, they have power to levy it, and the result is much to the advantage of the public, because the security is so good that they borrow their money at the lowest possible rate of interest, as a proof of which the whole debt of Manchester is now held at 4*l.* 0*s.* 10*d.* per cent.

202. (*Sir J. Thwaites.*) Do you know how they raised the money in Manchester?—By borrowing from anyone who would lend it.

203. By public tender or by private negotiation?—By private negotiation. They first borrowed a certain sum of money from the Exchequer Loan Commissioners, and they then found that they could borrow it in the open market at less interest, and they borrowed their money in the open market, and paid off the Exchequer Loan Commissioners, and they now borrow in the open market just as they find it convenient.

204. The interest being I suppose paid half-yearly?—I suppose so.

205. Is it by means of bonds or mortgage deeds?—By mortgage deeds. They also have what are called waterworks annuities. They agreed to give what they called an annuity for the purchase of the old Manchester and Salford waterworks in Manchester; it was not in the first instance an annuity, but they agreed to give so much a share by bonds carrying interest for the purchase of the old companies, and they purchased up these works by perpetual annuities of four per cent.

206. The first annuity was terminable?—Yes, in the sense of being purchasable at any time. Instead of continuing that they have turned it into perpetual annuities, and they give the parties four per cent.

207. I understand that the 35,000*l.* a mile includes 15 per cent. for extras?—15 per cent. for extras and for the land.

208. What part of the 35,000*l.* is for structural works?—The whole of it except the land.

209. There are extras which you have attached in your average of the cost per mile?—The whole sum in my estimate includes 15 per cent.

210. How much have you allowed for the purchase of land and severance, and injuriously affecting property?—About 840*l.* a mile.

211. That includes purchase and severance?—There is no severance where the work is covered, the land is all restored and given up again.

212. But there are places where the work is not covered?—Yes; and it includes the purchase and severance in those cases. Where the land is covered you purchase a wayleave, and restore the land to the owner on the condition that he does not build over it.

213. Have you taken into consideration the question of easement where you are in tunnel?—That price is the average, which includes the purchase of an easement on land in any case. A mere easement has been ordinarily purchased for about 100*l.* a mile. In Manchester we gave 100*l.* a mile for easement; in Glasgow we gave a great deal less than that; but in

Manchester wherever we occupied the land beneath the surface, restoring the surface, and restricting the owner from building over it, and allowing us to repair from time to time, we paid about 100*l.* a mile for that easement. Here I have 840*l.* on the average from one end to the other, much of the land being purely agricultural land, and much of it being worth very little. This map shows the line of conduit from the lakes.

214. (*Mr. Harrison.*) That may not be the course proposed by the promoters of that scheme?—No, but it must follow the contour of the country. I shall, however, be very happy that Mr. Hemans should describe it for himself. It is a singular thing that we so completely avoid all dangerous ground, and only just do so. The water will be conveyed in the manner which I have described, and by the sections which I have exhibited crossing the different valleys of the Severn and the Avon by syphon pipes which I propose to put down, namely, 4 feet cast-iron pipes. Pipes of the same size were put down in Glasgow with a fall of 5 feet in a mile wherever they occur, and putting them down from time to time as they may be required. I do not vary from the estimate which I have put in the appendix to my pamphlet; but as that only shows you first of all the cost for 130,000,000 gallons of water, I will give the gross cost for 220,000,000 gallons, and I can give you the gross cost for 300,000,000 gallons. For 220,000,000 gallons the summary of the cost would be as follows: at the reservoirs and works of collection upon the two branches, the green and the red district 1,080,287*l.*; the aqueducts from each of these districts to Marten Mere at the point of junction, taking the two together, would be 1,073,497*l.*

215. (*Mr. Prestwich.*) What is the length of those aqueducts?—19 miles and 21 respectively. The cost of the aqueduct from Marten Mere to London is 5,860,731*l.* The additional syphons on the main aqueduct, when required for 220,000,000 gallons of water, would cost 550,000*l.* For the service reservoirs near London I have allowed 500,000*l.*, which includes the cost of taking the water from there to a junction with the mains near Hyde Park, where you fall in with all the great mains of the various companies. Those figures make a total for 220,000,000 gallons a day of 9,064,515*l.*, that is exclusive of interest on money during the progress of the works, for which in the appendix you will find I have allowed 1,140,000*l.*, and it excludes the outlay for additional piping in the metropolitan districts when you come to use as much as 220,000,000 gallons, for which I have allowed in that appendix 600,000*l.*, making the total of my estimate in the appendix, which is in fact the same estimate as now for 220,000,000 gallons, 10,850,000*l.* including interest of borrowed money, and every other expense. The average cost of the aqueduct from the junction of the two branches to London, including the cost of syphons, is 38,000*l.* a mile, that includes everything. Dividing the 5,860,000*l.* by the distance it comes to 38,800*l.* a mile.

216. (*Sir B. Phillips.*) What is the distance?—151 miles, that is from Marten Mere to the service reservoirs at Stanmore for the aqueduct to convey the water. As to the 300,000,000 gallons of water, I can give you the additional cost of the aqueduct. Of course, inasmuch as I only estimate for the reservoirs which I have laid out, the district which I have appropriated will give you only 250,000,000 gallons, and therefore for 300,000,000 gallons you must go into an adjoining district, unless you have more water than I have assumed, and you make more reservoirs in the same district for the extra 50,000,000 gallons, which I have no doubt you can do. As the cost for each of these districts may be called in round numbers 500,000*l.* for about 125,000,000 gallons a day, an extra 50,000,000 gallons a day may be probably obtained for 250,000*l.* or 300,000*l.*, as the cost of storing and collecting in the district. Then the extra cost of conveying for the 151 miles will be about 4,000*l.* a mile, that is 600,000*l.* in round numbers, as the extra cost of the aqueduct for conveying the full quantity of 300,000,000 gallons, which is 80,000,000 gallons more than the former estimate. Then you have the further cost for enlarging the two branches, which I suppose would be 50,000*l.* The whole cost of procuring 300,000,000 gallons, including aqueducts, reservoirs, and all other cost, would be about a million sterling for getting an extra 80,000,000 gallons a day.

217. (*Mr. Harrison.*) Will you refer to the 1,100,000*l.* and state how much of that you calculate for reservoirs?—The reservoir at Llanwddyn, exclusive of land, is 54,256*l.*; the reservoir at Can-office is 45,546*l.*; the reservoir at Nant-e-Eira is 26,200*l.*; the reservoir at Rhyd-e-Gro is 77,193*l.*; then the reservoir on the Clywedog is 24,903*l.*; the reservoir on the Dulas is 25,000*l.*; the reservoir at Trefeglwys is 139,926*l.* Then 15 per cent. has to be added to all those figures. The total in the Bauw and Vyrnwy Valley is 538,000*l.*, and in the Severn Valley the total, including land, is 542,285*l.*; the land in the two cases comes to 325,000*l.*

218. Those figures amount to the 1,100,000*l.*?—Yes.

219. I do not see what portion of that sum is for the construction of the aqueduct?—You are now looking at the appendix.

220. Yes.—I am now giving it to you in a different shape. Looking at the appendix, you must add the 1,100,000*l.* in the one case, and the 1,100,000*l.* in the second branch together, which makes 2,200,000*l.*

221. Taking these minor aqueducts you have about 22,000*l.* a mile?—Yes, I should think about that.

222. You said that you would produce some sections?—This is a section assuming that at the same distance from London, whether you go to the lakes, or whether you go to Wales, up to that point the works in either direction are the same; and then it shows the difference of works from that point forwards, whether you go to the lakes, or whether you go to Wales. The lower section shows the character of the works up to the point at which we come to the reservoirs in Wales; and the upper section shows the character of the works according to the best line which I could lay out from near Stafford, (which corresponds with Bridgenorth in point of distance) to the lakes. This part, coloured pink, beginning at Bridgenorth, shows the line of works from there to the foot of the reservoir at Rhyd-e-Gro. (*The witness explained the section to the Commissioners.*) The section above shows the character of the country which must be passed through in getting to the lakes. The dark colour shows the coalfield; that is about the position where the line must cross the central ridge of the country if it comes down the Trent Valley, and east of the London and North-western Railway; from this central ridge northwards it goes through the new red sandstone till it comes to the Cheshire and Lancashire coalfield, and that is the general line which it must pursue until it gets to the final ridge at Kirkstone pass.

223. With regard to your own section, that is merely prepared from such data as you can get from the ordnance survey?—My part is not done from any marks upon the ordnance survey, except so far as the levelling goes, and from barometric observations over the hills.

224. But still for that you have certain data which are reliable?—Yes, it will be very nearly that. There are certain fixed points which we have, and the intermediate portion has been walked over with the aneroid barometer. This is the line which, according to my knowledge of the country, must be taken pretty nearly between one point and the other.

225. As I understand you, you do not propose to put in even an approximate section of the whole of your route?—I have not prepared one, but I will endeavour to do it if you wish me to do so.

226. To take an actual level from end to end where there are no contour lines on the ordnance surveys would cost probably several thousand pounds?—Yes,

J. F. Bateman, Esq.

7 Feb. 1867.

it would cost comparatively little in the hill district; but when you come into the swelling features of the centre of England, so much examination is required as to whether you should go up this valley or that valley, or take this or that direction, that it would be a troublesome matter to find out the very best line between there and Bridgenorth.

227. Might it not upon actual survey be found that the length of your line might be more than you have assumed?—It might be so, or it might be shorter. We have taken a line which according to our experience would be pretty nearly the line. I do not believe that it would vary much. We have certainly the district of country, and I believe that we have very nearly the line which should be taken. Of course I shall be very glad to have the whole thing taken, but what I have done has already cost me a good sum of money.

228. In a matter involving several millions of money, I think that hardly any engineer would give such an opinion as would decide such an important question as that of the cost, without having an accurate survey taken?—Not as to the precise cost.

229. Nor within a reasonable limit?—I believe that I can within a reasonable limit. I think that I know the cost of works of this sort so well, and that I have examined the country so sufficiently, as to be enabled to say that within a reasonable limit, say certainly within 20 per cent. above or below, I can give the actual cost of the work.

230. What do you say would be the cost of making the survey complete, would it be 10,000*l.*?—Yes, I think so, from 5,000*l.* to 10,000*l.* It would cost more than a railway, because in a railway you determine your line and accommodate it by inclination, but this work must be on such a uniform and gradual inclination as requires a considerable amount of examination.

231. (*Chairman.*) Can you give us what you estimate as the annual cost of the maintenance?—It would be so insignificant that I think it may be disregarded. The annual cost of the maintenance upon the Loch Katrine aqueduct is really nothing. It was my duty for some years after the works were completed to make periodical investigations, and they came to nothing more than pleasure excursions, and I could not reconcile it with my conscience to receive pay for pleasure excursions; there was absolutely nothing to do, no repairs were required, and after two or three years I gave it up, and gave it into the hands of the Commissioners.

232. (*Mr. Prestwich.*) But there you chiefly passed through very hard rocks?—We passed through the old red sandstone for about half the distance, which is very troublesome to deal with. I do not think that these works if properly constructed would cost any more to maintain, because it does not depend upon the strata themselves, but upon the actual construction of the work. There would of course be superintendence. I can hardly tell you what it would be. I have not gone into that question, but we should require one man at every reservoir; supposing that there are no repairs to do, one man would be quite sufficient, and then we should have a certain number of men stationed along the line of works for the purpose of inspection, and to see that everything was right, and to report how the thing was going on. The expense of that would not be very much. In Manchester we have about eight men at wages of about 30*s.* a week, and the same number in Glasgow.

233. (*Sir J. Thwaites.*) That is outside the area of distribution?—Yes. The Manchester waterworks are more troublesome to look after than the Glasgow waterworks. At Glasgow for a distance of 26 miles we have eight men; you would require about ten times that number. You would require from 70 to 80 men if the line of works was equally well manned, that is exclusive of superior supervision, which of course would have to be exercised.

234. (*Mr. Harrison.*) The whole of your open portion of work being lined with brickwork, do you think that it would be entirely free from all question of weeds growing in it?—Absolutely so.

235. And from any essential deposit?—There would be no deposit; there is no deposit at all in the Glasgow waterworks.

236. The Glasgow waterworks are covered from end to end?—Yes. When I say that there is no deposit, for a short time after the works were made there was a certain amount of sand which came in from the surface of the tunnel where it had been made in the new red sandstone. At the very top, perhaps from not having been made so tight as the rest, there was an infiltration of a very small quantity of sand; but if properly managed there would be no deposit whatever, the water would be delivered perfectly pure; it would run in a paved channel the whole way, and excepting a disintegration in the bricks or in the mortar which united them there would be nothing.

237. In process of time would not that disintegration probably take place?—No, not if your bricks and mortar were good. If the upper part were lined with a facing of Staffordshire blue bricks there would be absolutely no disintegration. The other part, which would be always under water, would require nothing but facing with good ordinary bricks.

238. (*Chairman.*) Have you any proposal to lay before the Commission as to how the money is to be raised to carry out this scheme?—That involves a large question. It involves the consideration of how you are to deal with the existing companies. My proposal is, I hope, pretty clearly explained in the pamphlet before your grace that the existing companies should be purchased. What I think ought to be the principle of water supply in London, as in all large cities, is that the waterworks and the distribution should be in the hands of the inhabitants themselves, and that they should be empowered to levy compulsory rates upon everybody occupying property within their limits of distribution, for the purpose of paying the interest on the requisite outlay and the cost of maintenance.

239. Would it be possible to carry out such a scheme as you devise, unless some such power as you have now sketched were given?—I hardly think that it would. At the same time I believe that it would be a very valuable undertaking if undertaken simply as a commercial transaction.

240. Upon the question of supply, and that this should be the only supply, as I gather from your evidence, has it ever occurred to you that there might be some danger in having so large a population as that of London and the suburbs solely dependent upon one supply of water, which yours would be. For instance, take the case of war, or take the case of a rebellion, or take any such extreme and improbable case, but though very improbable not wholly impossible, in which the supply of water might be interfered with or cut off, there would be 4,000,000 people without the means of having water?—I have considered that point. For ordinary cases of interruption I have provided by proposing reservoirs of so large a size near London, that within ten miles there would be storage to cover any possible contingency of interruption from accident or repairs required on the line of conduit, and by proposing that the works should be made in so permanent a manner that there would be no liability of their getting out of order; but as to the contingency of the water being cut off in the case of the country being occupied by a hostile army, I have no answer to give.

241. That never occurred to you as a possibility?—In that way you would have every city in Europe very much in the same position. Madrid is supplied with water from the mountains by a conduit of some 40 or 50 miles in length, and is solely dependent for its supply of water upon that conduit. Paris is now being supplied with water from a distance of 150 miles from the city, and although it may obtain some of its supplies from another source, yet the extension of the city, and virtually the safety of its supply of

water, will depend upon the maintenance of a conduit going out into the country 150 miles. I do not see how you can get over that. In Manchester, also, the conduit might be cut off and the supply interrupted, and in Glasgow the same.

242. Those are contingencies so remote that you have not considered them?—I think that they may be regarded as so remote that they may be well allowed not to weigh here. The quantity of water with which we are now dealing, namely, 300,000,000 gallons, is equal to the whole volume of the river Thames in extreme dry weather; and to pump out the whole volume of the river Thames, and to supply it to London, would be attended with so large an expense, that as compared with that it is worth while to incur the expense and the risk of this possible contingency, rather than to leave the city deprived of so valuable an addition to its comfort and its health as a supply of pure soft water.

243. (*Mr. Prestwich.*) For how many days would your service reservoir suffice?—For three weeks.

244. In case of long-continued frost what would be the effect on the supply of water to the reservoir?—Deep water scarcely ever freezes. Taking Loch Katrine, the winter of 1860-61, which was the first winter which occurred after the complete introduction of the water into the city of Glasgow, was a very severe winter; the temperature fell to 12 and 14 degrees below zero in the open air in the district along which the conduit was carried. But the temperature of the Loch Katrine water never fell lower than 39 degrees, namely, 7 degrees above freezing point, and there was not a particle of ice in any shallow or bay in Loch Katrine. After passing under cover, partly through tunnel and partly in a covered conduit to the Mugdock reservoir, 26 miles, the water acquired a temperature of 41 degrees, having gained two degrees in passing through the earth. So that where the water is principally carried underground, and where it is taken from deep reservoirs, the temperature would be such as to prevent freezing. If the water was wholly exposed in a shallow river, it would freeze, but with water ten or twelve feet deep, as would be the case here, and constantly going under cover, and being protected from excessive cold, I do not believe that it would freeze at all.

245. (*Sir J. Thwaites.*) There would be open cuttings?—I do not believe that the water would freeze there, because it would always be passing for half its length under cover.

246. And it would regain its temperature?—Yes.

247. (*Chairman.*) Have you made any calculation as to what amount of rate would be required?—Yes. That again involves the consideration of the payment to the existing companies; a rate of 10*d.* in the pound for domestic purposes, and of 2*d.* in the pound for public purposes, would pay the interest of the cost and dividend to the existing water companies at their present rate, or an equivalent, and the expense of management.

248. (*Sir J. Thwaites.*) The capital of the companies would be in addition to the 11,850,000*l.*?—Yes, subject to considerable deduction, because you would have a large amount of property which would then be found useless for the purposes of water supply, and which would be saleable, and you would save all the cost of pumping and eight separate managements.

249. (*Mr. Harrison.*) What is the present rate?—About the same.

250. (*Sir J. Thwaites.*) Would you save what you have stated as a matter of purchase?—If you became possessors of the present waterworks you would have a large amount of property which you could convert into money. For instance, a large portion of the income of many of the companies is derived from chief rents and not from water rents, and therefore that property would be saleable, it would not be part of the waterworks; and all the pumping engines and the very valuable land which in many cases they occupy would be saleable.

251. Assuming the capital of the companies to be 6,000,000*l.* or 7,000,000*l.* that must be added to the 11,850,000*l.*?—Yes, or its representative in interest.

252. That would make 18,000,000*l.* or 19,000,000*l.*?—It would,

253. And on that amount you assume what rate of interest?—Before coming to the net amount you must take the actual saving. If you capitalized the saving there would be a very considerable saving in the annual expenses of management, and so on, there would be the money derived from property and leases and useless machinery, and then you would have to pay the interest upon the money borrowed; and if you did not pay capital for the existing companies, you would have to pay either an arranged amount of interest or to secure them their dividends upon it, and to pay the expenses of management. That has all been very thoroughly and carefully gone into in the pamphlet before you.

254. (*Sir B. Phillips.*) Based upon the rateable value?—Yes.

255. (*Sir J. Thwaites.*) Would you permit individual shareholders of the old companies still to hold their property?—Yes.

256. And you would allow them to receive either a dividend or so much per cent. interest?—Exactly so. The shareholders in the Manchester waterworks had the offer of being paid a certain sum for their shares, or of receiving a bond for a perpetual annuity, and in the great majority of cases they preferred the perpetual annuity, which left them in the receipt of a fixed income, secured most amply upon unlimited compulsory rates on the whole property in Manchester, and those annuities are saleable in the market like any other stock and command a high price.

257. Supposing that you take the capital of the companies at 7,000,000*l.*, and that the holders of 5,000,000*l.* of that amount should elect to remain, you would have 2,000,000*l.* to add to your structural cost, bringing it up to 13,850,000*l.*, how do you propose to raise that money?—By borrowing in the open market, or by obtaining the money from Government.

258. (*Sir B. Phillips.*) In whom do you propose to vest the powers of construction?—That is a difficult point and requires a good deal of consideration, because there is no general board now in whom those powers could be vested, except that which is presided over very ably by Sir John Thwaites.

259. I understood you just now to say that the supply of water ought to be vested in the inhabitants themselves?—Yes, and at their cost and risk, and for their benefit. Of course the whole three millions of people could not have their finger in the pie, and therefore they would have to elect representatives in whom the undertaking should be vested.

260. In other words, Parliament would have to decide who should be the parties in whom it should be vested?—Yes. It would be equivalent to a municipal authority. In Leeds, and in Liverpool, and in Halifax, and in Manchester, and in a great many other places which I could name, the water supply is in the hands of the corporation, who have the power of levying compulsory rates within their own district, and of selling water like other trading companies to the outside districts which are not within their municipality. In Glasgow it is a water commission which is elected out of the corporation; the corporation is first elected in the ordinary way, and then out of the corporation is elected a body of commissioners, and they elect a water committee, and the water committee during their period of office are absolute masters of the waterworks.

261. (*Sir J. Thwaites.*) Do you think that there would be any difficulty in raising so large a sum of money, having regard to the period over which the works must necessarily be spread, probably eight or nine years?—No; I think that it is so much of an imperial question, that you might reasonably look in the first instance for aid, if it was required, from the

J. F. Bateman, Esq.

7 Feb. 1867.

Government, in exactly the same way as the Public Works Loan Commissioners afford assistance to many other undertakings. Their powers might be enlarged, and I think that in an undertaking which is of a national character you have a fair claim for assistance, if you find it necessary, just in the same way as there was an extension of the powers of the Public Works Loan Commissioners in the great calamity in the cotton district; but that need only be temporary, because I am sure that you would get the money lent to you by the capitalists of the country; nothing could be a better security if you adopted the principle of compulsory unlimited rates, which in my view is the right one.

262. (*Chairman.*) What is the rateable value of the property in London?—I am afraid that I cannot give you that quite accurately, and I think that Sir John Thwaites would perhaps have a better means of giving it than I should have.

263. (*Sir J. Thwaites.*) It is over 15,000,000*l.*—When I first took up this question some years ago it was 12,500,000*l.* and I did not then see my way to a satisfactory commercial result, and I dropped it. About 18 months ago I again considered it, and then I saw that the increase in the rateable value of property had been so great that it would be a profitable undertaking.

264. (*Chairman.*) You may take it that the rateable value of the property of the metropolis is now something over 15,000,000*l.*, or, in other words, that one penny will produce 62,000*l.*—Yes; therefore a shilling will produce about 720,000*l.*, a year, and you have in addition to that all the sale of water for trade purposes. But you must not take a shilling upon the whole of that; about two-thirds of it would be represented by dwelling houses, upon which 10*d.* would rest, and there would be 2*d.* upon the whole, and you would get a large income from the sale of water for other purposes. I estimated from the facts before me when I wrote that pamphlet, (and the estimate has been more than proved to be a correct one, by the increase in the value of property since that time,) that by the time when the works could be completed, and the water brought to London the rateable value would be from 18,000,000*l.* to 20,000,000*l.*, and I based the calculation as to the necessary amount of rate upon the assumed amount of 18,000,000*l.* at that time, of which 12,000,000*l.* would be upon dwelling houses, and 18,000,000*l.* upon all property.

265. (*Sir B. Phillips.*) The present rateable value of property produces something like 62,000*l.* a year at a penny in the pound?—Yes.

266. Why do you propose a rate of 10*d.* in the pound; 10*d.* in the pound would give 620,000*l.* a year?—Yes, but in round numbers you want 900,000*l.* to pay the interest upon the outlay, and the annuities, or dividends, or interest upon capital, which are represented by the existing companies and the management. In addition to the rate, you have water to sell for various purposes, and that is a very large amount indeed.

267. I do not think that we are charged here anything like 10*d.* in the pound for water.—You pay 1*s.* in the pound.

268; (*Sir J. Thwaites.*) And more than that in some places.—Yes, but it will average about 1*s.* in the pound. The increase of the population and of the rateable value of property in London is so rapid, that the rate to be paid by the inhabitants, as inhabitants individually, would not be greater than they pay for water now, although you expended 10,000,000*l.* in introducing the new supply. You would have the water of purer quality, and an unlimited supply at the same rate as you pay for your water now. We should have a water of superior quality, which by its softness would save an immense amount in other ways.

269. (*Mr. Harrison.*) What towns are there in the line of your aqueduct within reach, to which it would be desirable to supply water from this source?—There are no towns on the line which require water at all until we get into the midland districts, and then we get within 10 miles of the centre of a district which is probably the most difficult to supply of any large manufacturing or very populous district in England, namely, Wolverhampton, Dudley, Walsall, and Willenhall, and all the Staffordshire coal district, and Birmingham. They lie on the highest table-land in England, from which the water sheds in all directions. There are no hills near them from which they can obtain a supply of water, and I think that that district ought to be considered in any large scheme which would take the water near those places in its course. From Wolverhampton and from Birmingham the aqueduct would be about 10 miles distant. I am the engineer of the Wolverhampton waterworks. We pump water from the river Worth at Cosford Bridge, about 10 miles from Wolverhampton, and we raise it 400 feet. The line of aqueduct from the Welch district would be about 300 feet higher than the Worth at Cosford Bridge, where the water is now pumped from for Wolverhampton, and therefore there would be a saving of 300 feet, which is a very important thing. The intermediate district between Wolverhampton and Birmingham is supplied with water pumped from the new red sandstone at Lichfield, a distance of about eight or 10 miles. That is hard water. It is distributed by the Staffordshire Waterworks Company to a large and populous district. That water I think has to be raised about 300 feet. I know very little of the water supply of Birmingham, but I understand that it is in difficulty about its water supply, and I believe that its present supply by recent legislation is only granted to it for a limited period. I am not quite sure of that, but I think that it is the fact; Birmingham is certainly a town requiring a better supply of water, it being in a district which can hardly help itself. After that we do not pass any place which requires a supply.

270. (*Chairman.*) Should you be able to supply both Wolverhampton and Birmingham?—Yes, it is only a question of how much water they would abstract.

271. (*Sir J. Thwaites.*) You would have to increase the capacity of your tunnel?—A trifle down to that point. Of course it would be only reasonable that they should pay the additional cost of collecting and bringing the water to that point.

272. (*Chairman.*) Am I to understand you that you would have a sufficient supply of water to supply Birmingham and Wolverhampton and the metropolis?—There are 400,000,000 gallons of water a day available in the Welsh district. Birmingham, Wolverhampton, Walsall, Bilston, Dudley, Willenhall, Wednesbury, Stourbridge, and West Bromwich, which are all places where there is local difficulty in getting water, contain at present, according to the census of 1861, 522,000 inhabitants. They have supplies of water more or less. Wolverhampton has wells, and it is abundantly supplied with water. Walsall, Bilston, Dudley, Willenhall, and Wednesbury are all abundantly supplied with water from the sources which I have mentioned. I believe that Birmingham is indifferently supplied, and of Stourbridge and West Bromwich I do not know anything; but I can speak to 200,000 out of the 500,000 inhabitants being at present fully supplied with water. If they were left with their means of supply it would leave a population of 300,000, if all the supply of Birmingham was rejected, as the present population demanding a supply in that district. If you call it 500,000 persons, they would not require so much water per head as the London people would require. Giving them 20 gallons a head a day, which would probably be about their consumption (at Wolverhampton it does not amount to 20 gallons, I know the actual quantity there), it would be 10,000,000 gallons, and 10,000,000 gallons out of our large stock would not be very much.

273. Are there any other towns in the district nearer to the reservoirs?—Bridgnorth is the only place, except Montgomery, which is a small place. I do not know what its supply of water is, but it is close to the hills, and they could get it down very easily. I do not know the supply of Bridgnorth, it is upon the new red

sandstone, and close to the coal measures. Its population is perhaps about 5,000 or 6,000 and they would not require much water. From there to London there is no place of very great importance excepting Warwick and Leamington; you do not go far from those two places, and it might be that they might have a demand upon you.

274. (*Mr. Prestwich.*) You pass at no great distance from Coventry?—No, and Coventry I think is a place which might reasonably demand a supply. I believe that it is abundantly supplied now, and it gets it from the new red sandstone. I do not know much about that supply, it is in Mr. Hawksley's hands.

275. (*Mr. Harrison.*) Is Oxford at all within reach?—No, Oxford is too far off. Oxford is a town which is not well supplied, and cannot be well supplied with water, except by taking it from the Thames; it does not take it from the Thames now, it takes it from water collected in a gravel pit which was excavated by the Great Western Railway Company when they made their railway. The water collects from the hills in this gravel pit, and is supplied from there. It is not bad water, excepting that it is hard.

276. (*Chairman.*) You are aware that there are other districts from which it is proposed to supply London; there is the Lake district?—The lake district I have very slightly referred to, and there is the Derbyshire district, which will be laid before you. I have avoided referring to those districts except to bring out my particular scheme. Perhaps I may ask to be permitted, in case of any necessity arising, to answer or to observe upon any scheme which may be proposed, as I invite anybody to do who is desirous of saying anything in criticism upon the scheme which I have laid before your grace. I think that it is only fair that any objection which can be raised to my scheme by anybody should be raised, and that I shall have an opportunity of examining it afterwards, and perhaps in like manner I may be permitted, if need be, to observe upon any other scheme.

277. We now come to the manufacturing districts. Will you show us the ordnance map giving the waterworks and gathering grounds of some of the large towns? (*The witness produced the same.*)—It is not quite so fully prepared as I should wish it to be. The manufacturing district may be said to commence with Preston in the north. The collecting ground of Preston I have not yet marked. Then there are various other places, and there is also Liverpool. I propose upon this map to show you all the gathering grounds. I am either engineer for, or am connected with, most of the waterworks. The map is not fully prepared, but I can tell you the population of all the large towns and the condition of their present supply, and their means of giving it. As far as I can I will mark the extent of gathering ground to each district, so that you will be able to see how much of the district is occupied, and how far it can help itself. Manchester contains, including the population which it supplies with water, in round numbers, 600,000 persons. It gives a supply of 12,000,000 gallons of water a day, and it has a supply of 25,000,000 gallons a day, therefore that place is fully supplied. Stockport has a population of 70,000 persons, for which there is an abundant supply, partly by taking water, by arrangement, from the Manchester waterworks, and partly by gathering grounds on which a portion of the works authorized are constructed, with power to construct further works not yet constructed, because the water is not yet required, and therefore it wants no additional supply. Bolton has a population of 85,000 persons, it was formerly well supplied. I have executed some of the works for Bolton, and was for a long time their engineer, but it fell short of water three or four years ago, and two sessions ago I think we got an Act for a very considerable extension of water for the supply of Bolton from the hill district, which will give them, and all dependent upon them, a full supply for many years to come. I was also the engineer of the Accrington waterworks. Accrington has a full supply; I cannot now give you the quantity, but only five or six years ago new works were constructed there. Blackburn has been rather short of water, in consequence of works which were authorized six or seven years ago not having been so quickly carried out as they ought to have been. I am engineer of the Blackburn waterworks, and we are now executing works for a complete supply of Blackburn and its district. Preston has not long ago constructed waterworks from Longridge Fell by which it has an abundant supply of water, and it is close to a water-producing district from which it can get any sufficient quantity. Over Darwen, for the waterworks of which I was engineer, has an abundant supply of water, and the quantity from the gathering grounds is only partly occupied. Ashton-under-Lyne, with a population of 90,000 persons, is now constructing works for the supply of that town and of Stalybridge and Dukinfield, in a valley which has often been a point of contest with water companies adjoining the Manchester waterworks district, from which an abundant supply of excellent water can be obtained. Fleetwood, with Blackpool, Kirkham, and Lytham, has just constructed waterworks from which it gets an abundant supply. Heywood is a manufacturing place between Bolton and Bury and Rochdale, which some years ago got an Act of Parliament and works have been constructed by which I believe it gets a sufficient supply of water. Mr. Cawley is the engineer of those works. Wigan is I believe indifferently supplied; it is upon the richest part of the Lancashire coalfield, and it gets only a so-so supply of water from a questionable district. That is a place which may require an additional supply. I am the consulting engineer of the Oldham waterworks. Oldham is now about completing works which have been in course of construction from some years, by which it will get an abundant supply of water. At Warrington I constructed waterworks. They have I believe pretty well exhausted their supply, and may require an additional supply. I also constructed the early waterworks of St. Helen's. They have extended their works, and I am not quite sure whether they do not get a supply of water from the Liverpool waterworks by a conduit-pipe which passes close by. They may, however, require an additional supply. There is an adjoining place, namely, Widness, on the Mersey, near Runcorn, which is a very populous place. It is a chemical manufacturing district, and there I am advising them to seek for a supply of water in the new red sandstone, and they will get an abundant supply of water. St. Helen's also lies partly upon the new red sandstone, from which it can get a supply of water. Rochdale was in Parliament last year for extensions, and I believe it will get an abundant supply. Bacup lies quite in the hills, from which an abundant supply can be obtained, and I believe that it will not require any additional supply. Burnley has been recently constructing waterworks, not on a very large scale, but they are in a district close to the hills, from which almost any extension may be obtained. Bury has constructed very considerable waterworks from time to time, and has I believe an abundant supply; at all events it is capable of very large extension. Liverpool, which has a population of some 500,000 persons, is taking a considerable quantity of water, and it gets a portion of it from wells in the new red sandstone that is about one-third of its supply, it gets two-thirds of its supply from the hills in the district known as Rivington Pike. They for the last two or three years have been short of water, and they are now proposing to go, at all events it has been proposed and debated, and probably will result in their going to Bala Lake for a supply of water to Liverpool. They consume very much more water in proportion to the population than any other town in that district, and they are short, and they are prepared to expend a considerable sum of money in going to Bala Lake.

278. (*Col. Harness.*) Has Rivington Pike given them less water than was expected?—Yes. The estimate of Mr. Hawksley, who was the engineer, was 15,000,000 gallons a day. My estimate was

J. F. Bateman, Esq.
7 Feb. 1867.

J. F. Bateman, Esq.

7 Feb. 1867.

12,000,000 gallons if they had storage enough, but unfortunately they had not storage enough, and during a portion of last year and during two preceding years the quantity fell to about 11,000,000, 10,000,000, and under 8,000,000 I believe in the last year, but that was principally for want of storage. Last year they were in Parliament again for the purpose of creating additional storage, and for purchasing the water of a stream called the river Roddlesworth.

279. Do you know what storage capacity they have?—About 400,000,000 cubic feet altogether, and they have a drainage ground of 9,000 acres. Of Clitheroe, which is a small town of 10,000 inhabitants, I do not know anything at all; it is close to the hills. Colne with 6,000 persons is in the same position. Middleton, with a population of about 10,000 persons, is I believe dependent for its supply of water on Oldham. Haslingden, a very flourishing place in the centre of a large manufacturing district, in the valley of the Irwell, has waterworks recently constructed; and the people there have in their opinion so much surplus water that they propose to take it a long way into the country to those places which have not a supply. Leigh and Tyldesley are I think within the limits of the recent Bolton Act, but those are places which have been proposed to be supplied by the Haslingden waterworks. They are a good deal mixed up with the property of Lord Ellesmere, and there was a proposal not long since, which came before me as his lordship's engineering adviser, with reference to the supply of that district. Ormskirk, which is away from the manufacturing district, but still in Lancashire, is supplied by pumping out of the new red sandstone by works constructed by Mr. Rawlinson. Padiham is a small place close to the hills. Lancaster, with 16,000 persons, has its supply of water from the hills above. Southport has a supply of its own from the new red sandstone. Ulverston is in the mining and lake district quite away. That I think gives pretty nearly a list of all the manufacturing places north of the Mersey. In all these waterworks, with few exceptions, those exceptions being I think Stockport and Liverpool partially, water has been given as compensation for the abstraction of water. In that way the streams for manufacturing purposes have been increased, the value has also been increased, and the prosperity of the country as a manufacturing country depending upon power, so far as water power is serviceable for those purposes, has been enhanced. I have always contended, particularly in manufacturing districts, that that is the right principle, in a national point of view, upon which to pay compensation, for if, as at Liverpool last year, you grant powers to abstract the whole water of a river not being now employed for manufacturing purposes, and therefore not now contributing to the industry of the country, you absolutely deprive it of all future chance of being used for those purposes, you destroy the value of that property, and destroy the working power of the country, whereas, if the floods are impounded and partially delivered, so as to increase the working volume of the stream, you increase that working power. Indeed I think that it was altogether wrong that Liverpool should have been allowed to go to this district, because Darwen, Accrington, Blackburn, Wigan, and many other places are large and flourishing towns, closely contiguous to the Liverpool gathering grounds, the whole district having a dense population where the inhabitants can only look to this little cluster of hills for a supply of water. Liverpool has put its paw upon that supply and has very considerably limited the power of the surrounding districts getting an additional supply of water; and I would venture to suggest, as it is a national question, that if Liverpool should be permitted to go to Bala Lake for water, where it may take water without injury to any manufacturing interest, those hills being as it were the great manufacturers of water, the Rivington district should be held liable to have water abstracted from it for the supply of any neighbouring town which could not otherwise get a supply of water. I will give you this in greater detail, but I show you as nearly as I can give it to you the general position of the manufacturing towns.

280. (*Chairman.*) Will you be kind enough to supply us with reductions of the maps upon the walls which can be appended to our report?—I will endeavour to do so.

281. Can you also favour us with a section of your line from Loch Katrine to Glasgow?—Certainly.

282. Have you considered the effect which your scheme would have upon the navigation of the Severn?—The Severn I think is not navigable beyond Tewkesbury. There is a lock at Tewkesbury, and the last weir upon the river is at Tewkesbury; how far it goes above that I am not aware, but so far as the river is above the tideway any effect whatever would be beneficial, because while it diminished the floods to a very limited extent it would increase the dry-weather volume of the river.

283. Below that point you get into the tideway?—Yes; and I must tell you frankly that that is the only point on which I think it possible that parties may oppose this scheme with a show of reason, namely, those who may think themselves damaged by reason of the destruction of the present small amount of scouring power which would result from the diminution of the floods. The Severn is a river with an enormous amount of tidal water flowing both up and down, and any diminution of its scouring power derived from the hills will not be much; but it is right to say that there may be some mischief arising from that cause in the view of some parties, and as far as I can see that is the only point upon which any people can raise a reasonable show of opposition.

284. Your point is that the diminution of the scouring power would be so small that it would not be appreciable?—That is my opinion. When we proposed to take water from the river Forth and to turn it into the Clyde, we were opposed by the people interested in the Forth on that very ground, and we had lawyers' speeches (I do not know whether we had actual evidence) that St. Margaret's Hope, where the water is 60 feet deep, was in danger of being ruined. I had tide gauges and calculations made, and I showed how small any abstraction would be in proportion to the volume of water flowing up and down, and I satisfied the Committee that no mischief would be done, and there has certainly been no mischief yet.

285. You can speak with great confidence, from the experience of the Forth, that there would be no damage done to the Severn?—I do not believe that there would be any damage done to the Severn; above the tideway it would be improved.

286. Supposing that your scheme was carried out, how long would it take before it was completed?—Supposing that authority were now given for its execution it would be quite impossible to prepare working drawings and specifications for the commencement of the work in less than twelve months, and then with very great exertion, if there was no difficulty about money, and by proper arrangements, I think that it would be possible to execute the work in perhaps four years; but I think that it would be safer to assume that the shortest period within which the work might reasonably be calculated to be finished would be five years, that would be six years from the authorization to the introduction of the water. I may mention that in the case of the Glasgow waterworks, which occupied as long a time as these works would be likely to occupy, except that these are on so much larger a scale that they would be rather more difficult to handle, the time occupied from obtaining the Act was from early in the summer of 1855 to the early portion of the year 1860; about five years, or a little short of five years.

The witness withdrew.

Adjourned to Wednesday next at half-past 11 o'clock.

Wednesday, 13th February 1867.

PRESENT:

HIS GRACE THE DUKE OF RICHMOND IN THE CHAIR.

Sir JOHN THWAITES.
Colonel HARNESS.
Alderman Sir BENJAMIN PHILLIPS.
THOMAS ELLIOTT HARRISON, Esq.
JOSEPH PRESTWICH, Esq.

GEORGE WILLOUGHBY HEMANS, Esq., examined.

G. W. Hemans Esq.
13 Feb. 1867.

287. (*Chairman.*) You are a civil engineer, and a member of the council of the Institute of Civil Engineers?—Yes.

288. Have you considered the best mode of obtaining water in the high districts of England and Wales with a view to supply the metropolis?—Yes.

289. And also to supplying other towns, and the intervening population?—Yes.

290. Mr. Richard Hassard, also a civil engineer, joined you in those schemes?—Yes, he has.

291. Which schemes he originally suggested to you, did he not?—Yes.

292. Since that have you conjointly with Mr. Hassard considered which would be the best mode of supplying water?—We have considered and worked up the scheme which is now before the Commission.

293. Have you any means of telling us from official documents the quantity of water which is used in London?—Yes.

294. With regard to the quantity of water which is used in London, is it a fact, taking it generally, that London at the present time consumes about 100,000,000 gallons per diem?—That quantity is accepted by all parties, I believe, as being the authentic quantity which is consumed in London.

295. And is it your opinion that London will in the course of a short time require that quantity to be very much increased?—We assume that at the present rate of progress London will increase 50 per cent. in the next 20 years, which would bring the population up to 4,500,000 instead of the 3,000,000 that there are at present, and it is believed and I believe that water is at present very inefficiently given, especially to the poorer inhabitants of London.

296. Are you of opinion that in the course of a short time the supply to London will require to be doubled?—At least doubled; in fact I may say that instead of 100,000,000 gallons it will require eventually 300,000,000 gallons; but I must add that I consider that provision ought to be made for 250,000,000 gallons at least.

297. Having stated that the present quantity is 100,000,000 gallons, and that in all probability it will require to be doubled, have you fixed in your own mind any period within which that supply ought to be so increased?—I think that by the time any great works could be completed so as to bring water either from the Welsh mountains, or from the Cumberland lakes, the necessity would arise for a very large proportion of this increased supply.

298. May we take it generally that you are of opinion that within the next 10 years it will be necessary to have the supply of water doubled?—I would hardly perhaps go so far as to say that a full double supply would be necessary within 10 years, but I am certain that more than half of that additional 100,000,000 gallons will be required in 10 years.

299. Assuming that you require to increase this supply, and that you propose to bring it from the higher districts of the country, how would you propose to do so?—Before I answer that question, would your Grace allow me to add something to my last reply, in which I said that in 10 years perhaps it might not be necessary to have the whole of the additional 100,000,000 gallons. I know this, that if it be true that the Board of Works will require some 42,000,000 gallons a day for the mere purpose of flushing the sewers, which has been publicly stated, then I think that the whole of the additional 100,000,000 gallons ought to be provided by the end of 10 years from the present time, if that large demand be necessary.

300. Having given that explanation, how would you propose to bring this very large quantity of water to London; will you tell us from what part of the high district you would propose to bring it?—The locality fixed upon by Mr. Hassard and myself is that of the Cumberland lakes, which possesses the only authentic record of a rainfall sufficiently large for the purpose, and which, although 270 miles from London, and not 310 as Mr. Bateman made it by the route that he took, may be said to be ready, to a certain extent, for the storage of water. The three lakes which we propose to deal with, consisting of Haweswater, Thirlmere, and Ulleswater, may be looked upon as natural reservoirs of water, in contradistinction to the numerous artificial lakes which Mr. Bateman proposes to make, and I trust that at this point we may express a hope that the Commission will visit both the localities, because it is a great part of our plan that we believe the surface from which water will be gathered, and which now pours into those lakes, is a great deal cleaner and freer from impurity than the surface of the Welsh gathering ground; we believe that those natural lakes of water are better suited to deliver water to towns than the artificial reservoirs which will be made over a cultivated district, now occupied by villages, churches, graveyards, and farms of considerable value; and we also believe that the water on the Welsh hills, in comparison to this which we propose, will be turbid, and that it will require filtration. The rivers have been visited, and Mr. Hassard, who will follow me in evidence, will prove that the water that he saw in the Welsh district was turbid, and would require filtration in coming to London. I mention all this at starting, before describing the method of dealing with the lakes in Cumberland, because we are very anxious that those distinctions should be impressed upon the Commission, it being obviously almost foolish to suggest a plan requiring 270 miles to bring water to London if an equally good one can be found within 183 miles, and having besides the very great scientific position of Mr. Bateman to contend with in this matter, who really has a reputation as a water engineer which neither Mr. Hassard nor I possess, we are very anxious to impress these salient points upon the Commission, and we hope that they will themselves view the grounds. I will now, with the permission of the Commission, proceed to refer to the map on the wall, and describe the mode of dealing with those lakes.

301. Before you refer to the map, let me ask you would you require, in order to bring this water to London, to create artificially a pure water river of 30 feet wide and 10 feet deep?—It would be necessary to have an artificial conduit consisting alternately of tunnels, open cuttings, and pipes equal to those dimensions, in fact a river of not less than 30 feet wide and 10 feet deep in round numbers, flowing at the rate of about a mile and a quarter per hour.

302. (*Mr. Harrison.*) What would be the inclination per mile?—The inclinations will vary. Taking the whole distance, we could give very nearly the inclinations which Mr. Bateman gave, which were, I

G. W. Hemans, Esq.

13 Feb. 1867.

think, 14 inches per mile, and six inches according to circumstances; but we have chosen smaller inclinations, believing that the safety of the aqueduct is greater with a small current than with a rapid current, and we adopt inclinations of six inches, and in some cases four inches, and for pipes a fall of from one foot eight inches to two feet, where pipes are used, in the form of syphons.

303. Do you not propose in all cases to line your conduit?—The conduit will be almost always lined, but not always so expensively, we think it not necessary to line it quite so expensively as in Mr. Bateman's project. He adopts a brick dish or conduit, I think, the whole way. We do not think that that is necessary. We know that the New River and many other conduits, and Mr. Bateman's own conduit, I think, to Glasgow, is not lined in that expensive way with brickwork, and we think that it rather tells (although I do not wish to insinuate that Mr. Bateman put it in that way) against our project, where the mileage is high, to put the expense on the culvert and leave it less at the lakes. We have no doubt that our conduit will be sufficient. We can exhibit the drawings of every section of it either now or later, but I propose leaving those details to Mr. Hassard, who has worked them up a great deal, and merely to give the chief points myself.

304. (*Chairman.*) It would nesessarily require, would it not, a very large rainfall, and storage in vast reservoirs, to keep up this river which you have now described during the dry seasons of the year?—Yes. In wet weather this river will be kept up by the rain that falls in the district, but in dry weather it is quite clear that the water must be heaped up in the mountains to supply the river, and that storage is what we possess in those lakes which I am about to describe.

305. Those lakes must be high enough for the water to gravitate to London?—Yes, they will be high enough to command the highest houses; 220 feet is the height that we obtain near London, at the high ground near Edgware.

306. Before you go into the details of the scheme, will you have the goodness to state what your view is as to the description of ground which is best adapted for forming the collecting ground?—I think all water engineers are agreed that the gathering ground which is to supply pure water ought to be as clean as possible; that it ought to be of that rock which gives soft water, and not, as the limestones do, water with a considerable degree of hardness. What the Silurian slates, which the Cumberland lakes are in, possess is soft water, an analysis of which will be laid before the Commission by Professor Way; and we find that the mountains round those lakes are particularly clean and rocky, that there is little or no cultivation, and that their height is such that there is never likely to be cultivation upon them. Our gathering ground is, on the whole, some hundreds of feet higher than the average of the proposed gathering ground in the Welsh mountains, and that is one reason which will always prevent cultivation from injuring the water which falls upon it, and therefore the supply will always continue to be clean and pure.

307. Would the water which you propose to supply, in your opinion, require any filtration?—We are convinced that no filtration whatever will be necessary with these waters from the lakes, whereas we think it will be necessary with the Welsh waters.

308. (*Mr. Prestwich.*) Does not the water come from the peat?—There is very little peat in the lake district.

309. (*Chairman.*) Have you a record of the rainfall in the lake district?—A record of the rainfall in the lake district was kept by Dr. Miller, who is now dead, but who kept the gauges for a great number of years, and the results have been recorded in various philosophical transactions. Since his death other observations have been made, and the gauges have been kept up, and are still going on to a great extent in those mountains. We are prepared to prove through Professor Symons, who has made it his business to publish works on meteorology, and to study especially the mountains, that the rainfall may be taken on the mean as 77 inches throughout our districts, that the minimum is over 60 inches, and that the longest drought on record during 44 years has been under 70 days.

310. Do you think that you could supply with water any of the places on the road between the lakes and London?—We believe that a number of towns on the road between the lakes and London could be supplied by this river of 30 feet by 10, including Liverpool.

311. What amount of water could you supply, or should you propose to supply by your scheme, to the places on the road, including Liverpool?—There would be no difficulty in getting from that district 300,000,000 gallons per day by extending the works, although we have only contemplated, at the present moment, 50,000,000 gallons in addition to the London supply at 200,000,000 gallons.

312. But how should you propose to devote that 50,000,000 gallons?—We have not made any apportionment, and it would require more time to ascertain what quantity each town might require or agree to take, but 50,000,000 gallons in round numbers is assumed to be ready for that purpose, and 200,000,000 gallons to go on to London.

313. (*Sir B. Phillips.*) Is 250,000,000 gallons supposed to be the total supply?—No, we are able to get from that district 300,000,000 gallons, but passing, as our conduit will do, close to the source of the Liverpool water supply, which is Rivington Pike, if it should happen that the Liverpool people would take the water from us, we being close to them, then instead of Bala Lake being taken to Liverpool it might be thrown into the London channel to make up for the quantity which was given to Liverpool.

314. (*Chairman.*) How is Liverpool at present supplied?—From a place called Rivington Pike, which I think is some 15 or 20 miles from Liverpool, from the Sandstones to the north, in a direction which we cross with our conduit.

315. Do you think that you can supply better water and at a cheaper rate to Liverpool than by going to Bala Lake?—Yes, I think so.

316. Is it the intention of the corporation of Liverpool to go to Bala Lake for the purpose of getting more water?—They have come to no resolution as yet, but it has been suggested to them by Mr. Rawlinson and other engineers.

317. (*Sir B. Phillips.*) You started by stating that the present supply to London was something like 100,000,000 gallons per diem, and supposing that the Board of Works required 46,000,000 gallons for the purpose of flushing the sewers, the 200,000,000 gallons would really be wanted for London within a given time?—Yes, within 10 years certainly, that is the quantity which will be required.

318. When we speak of the quantity of 250,000,000 gallons only, taking into consideration the growing wants of London, and putting your estimate as low as 200,000,000 gallons, do you think that it would be desirable to interfere with any portion of that 250,000,000 gallons which you propose to bring to London for the purpose of supplying any other city?—I will show the Commission presently, when I describe the lakes, that we could take 300,000,000 gallons altogether from that district alone without considering Bala Lake, and that if a conduit were made in the first instance big enough, 300,000,000 gallons could be taken to London, and part of that could be sold on the way instead of taking only 250,000,000 gallons and spreading part of that on the way. There are four districts which we contemplate using, as I shall show when I describe the lakes, of which only three are proposed to be taken now, and the fourth when it may be required.

319. (*Chairman.*) What would be the extent in square miles of the gathering ground which you pro-

pose to take?—177 square miles in the present project.

320. Is there any means of calculating with any degree of certainty what amount of rainfall would be necessary over that area to supply 250,000,000 gallons per day?—That has been calculated, and the quantity is less than one-tenth of an inch per day over the whole surface. I have put it at one-tenth of an inch for the sake of round numbers, but it is in reality a decimal less than that; one-tenth of an inch over 365 days would give, of course, 36½ inches in the year, and if we take for evaporation and absorption 12 inches more, which is the usual quantity to take, 48½ inches would be required to give us the 250,000,000 gallons. Beyond this a certain quantity would be required for compensation, and as we are able to prove, a rainfall of 77 inches, the difference between 48½ and that would go to compensation, that is to say, 28½ inches would go to compensation to supply the rivers that we take the water from. And that is a very large quantity indeed, for as Mr. Bateman stated the compensation need not be taken at more than one-fourth, and this would be considerably more.

321. (*Mr. Harrison.*) Your minimum rainfall is 60 inches, is it not?—I think it is 61 or 62 inches, but Professor Symons will give that exactly; however, it is over 60 inches, so that when the rainfall was at the minimum the compensation would be less, but still ample for that district.

322. (*Mr. Prestwich.*) Do you reckon upon having all the 77 inches of rainfall available with the exception of 12 inches?—No, we take 36½ inches.

323. You allow 12 inches to be lost?—Yes.

324. Then you reckon 28½ inches, do you not, for compensation?—That is the difference between the loss of what we take and the rainfall of 77 inches, assuming the rainfall to be 77 inches.

325. Then you consider that the 28½ inches are available, and the 48½ inches, with the exception of 12 inches which would be lost in evaporation and absorption?—Yes.

326. That is to say, you consider the whole of the rainfall available with the exception of 12 inches?—Yes.

327. Do you consider 12 inches enough to be allowed for evaporation in so large a fall as that?—The more rocky and bare a mountain is the less absorption there is, and probably less evaporation, because the water will all run down so quickly in a rocky district like that that there would be less evaporation than in a cultivated district, but it will be observed that there is an ample margin to spare even if we allow a larger evaporation. There is a very large margin, because 28 inches is a very large amount of compensation, and part of that might go.

328. The absorption would be very small in that district, it being very rocky, but what mode have you of arriving at a conclusion as to the evaporation?—From experiments upon evaporation. There are not many good experiments on the subject, but it is quite clear that the steeper and more rocky a district is the sooner the water runs to the reservoir, and the less time it has to evaporate on the way.

329. Have you gauged any of the streams in the district?—No, we have not gauged the streams, but we have measured the capacity of the lakes and the reservoirs and the rainfall, and it does not seem necessary to gauge the rivers with these data. If you have the absolute amount of rainfall and the acknowledged storage to hold it in the gauging of the rivers does not seem to be absolutely necessary.

330. (*Sir J. Thwaites.*) How do you arrive at the net result except by gauging the rivers?—We know the number of square miles upon which a certain quantity of rain falls; we know the capacity of the only place where this rain can go; and we know what is usually considered the proper allowance for evaporation and absorption.

331. But how do you arrive at the conclusion that 12 inches is the proper amount to allow for evaporation, seeing that you have 4,000 acres of surface exposed, from which there will be an evaporation of probably six or seven inches?—With regard to that I can only say that a great number of experiments and gaugings have been made in a number of districts, and that if you take the worst districts, like those districts in which the water lingers, as it does in bogs, where it is held by the spongy nature of the soil, and where a great amount of evaporation goes on, and gauge what comes off, and find the maximum and the minimum; and if you take the very best district for evaporation, for instance the roof of a house, where there is no evaporation, because when the rain falls it runs away and gets into cisterns at once; and if you strike a mean between those two, that mean will amount to 12 or 14 inches. Those are the data which we go upon, and which are generally accepted.

332. It comes to this, does it not, that you have a lake of a given area, which you call your storing power, and you have a given amount of rainfall and a given amount of absorption and evaporation?—Yes.

333. The best practical proof of the correctness of the amount of absorption and evaporation would appear to be to test the quantity at the point of discharge of the lake, because you would get the net result; but the question which my colleague put to you was this, whether you have gauged the outfall of those lakes so as to ascertain the daily discharge from them, and whether that daily discharge was equal to the amount which you calculate will be required from the 48 inches which you have at your command?—I entirely concur with what is stated in the question, namely, that if you want to ascertain absolutely the evaporation or loss in any given district, the best test is by gauging the water that flows off it; but it must be remembered that here there is a very large excess of rainfall, and if you have 28 inches, as is supposed, or anything like it to run off, there is no necessity for that extreme nicety in the first instance in an inquiry like this. There is no doubt that those great rivers which are rapid streams and liable to great floods might be gauged, but it would be a very tedious and costly work, rather too much to expect in the initiation of a project like this, especially when we feel that there is such a margin of water, and that no important result depends upon that point.

334. Have you walked over the ground yourself?—Yes.

335. Have you examined carefully Haweswater, which is the highest elevation?—Yes.

336. Did you examine the discharge at the lower end of the lake?—Yes.

337. Did it not occur to you that it was exceedingly small compared with the gathering ground?—The discharge varies considerably. It will be small in dry weather, and full in wet weather. But I was about to explain that an immense amount of water that does not run through now will be brought to Haweswater; the waters that flow in other directions we propose to gather and throw them into Haweswater.

338. But taking the gathering area due to Haweswater itself, and taking the whole leakage of the whole of that district and the farms around it, did it not occur to you that the discharge from the lake itself was exceedingly small?—There was a very large river coming out of it when I was there, and undoubtedly that would vary; but the actual gathering ground of Haweswater is nothing like that we propose to make.

339. I am now speaking of the discharge from the lake itself?—But you will observe that when we have brought the water to it, that is to be added to it, it will discharge an immense deal more than it does now. Its present gathering ground individually is comparatively small, but we propose to make it a gathering ground of 38 square miles by the process which I am about to explain.

340. Then, in point of fact, with regard to absorption and evaporation, you have no positive rule to

G. W. Hemans, Esq.

13 Feb. 1867.

guide you in making the calculation as to how much would be taken from the 77 inches of fall?—I would hardly admit that because by the general rule which is adopted by engineers it would vary from 12 to 19 inches, according to the nature of the ground. I believe that 19 inches is quite the maximum, and the minimum may be called 11 or 12 inches, and anything between those figures may be taken according to your judgment, and according to the district in which you are working.

341. (*Mr. Prestwich.*) In Cumberland and Wales are there any large peat beds or bogs that absorb the water?—No.

342. But the mountains in both districts are covered, are they not, with heath, which, though not very thick, is very retentive of water, and the water is held there and exposed to a considerable amount of evaporation?—I think that great portions of our district, which are extremely lofty, are almost denuded of heath. There is a great deal of heath in the district, undoubtedly, but I think it will be found that great portions of it are bare rocks.

343. (*Sir J. Thwaites.*) With regard to the absorbing quality of the peat, that would depend, would it not, upon whether the basin was really full, because if it were filled that absorption would stop?—But the peat does not always lie in basins.

544. There is a considerable amount of peat in the contemplated district, is there not?—We think not. I have been over the district myself, and Mr. Hassard will tell you that he has been over it more than once.

345. Take Bampton Common, just above Haweswater. There is a large quantity of peat there, is there not?—There are peat beds, but in comparison to the enormous area of 177 square miles they are small.

346. And between Haweswater and Ulleswater, is not the whole of that district full of peat?—If you walked it over I think you would find that you could hardly say that the whole of it was full of peat.

347. I do not say the whole of it, because the upper part is a ridge of rock cropping out of the surface; but there is a considerable amount of peat there?—I am very glad to see that you know the district so well, and I hope the whole of the Commission will visit it, and apply their observations to these matters.

348. (*Chairman.*) Will you describe the district from which you propose to bring the water, the size of the reservoirs, their position, the direction in which the natural drainage of the ground goes, and also generally what the soil is composed of?—We propose using the three lakes of Haweswater, Ulleswater, and Thirlmere. Haweswater Lake is 694 feet high, and its surface is 683 acres. Ulleswater Lake is 480 feet high, and its surface of water 2,300 acres. Thirlmere Lake is 533 feet high, and its surface is 875 acres. The Commissioners will observe that Haweswater and Thirlmere are both considerably higher than Ulleswater, and I was about to show that both of them are simply used for the purpose of keeping up the supply in Ulleswater, and not to be drawn from themselves towards London. We commence at a point called Cooper's Green by making a catchwater conduit which will convey all the water of this district of Swindale, and above it to the point marked on the map where a reservoir may be made.

349. When you say that a reservoir may be made do you mean that it will be made?—It may not be necessary to make it at once, but it can be made whenever the supply of 250,000,000 gallons is required. If the supply remains at only 200,000,000 gallons, that reservoir of course may not be required. Still it may be useful hereafter.

350. What would be the size of that reservoir if required for 250,000,000 gallons?—I shall get Mr. Hassard to make a note of that, and give it to the Commission. We have only considered it at the present moment as a thing that may be required. We commence by taking up the water at Cooper's Green and Swindale Common, and carrying it to a point on Swindale Beck, and then from Swindale Beck we continue that conduit into Haweswater, and throw all the water of that district of Swindale Common into Haweswater. We then go to Helton Dale Beck to the north of Haweswater, and take in Gill Beck and Hows Beck, which are two streams above, and we throw them with all the district belonging to them also into Haweswater, and Haweswater will be raised 42 feet in order to contain those additional waters. We then from the embankment which supports those waters let off a sufficient quantity to keep the supply of the river Lowther, which we have originally taken at Cooper's Green to carry the water down the river Lowther, and pass Lowther Castle, which is the property of Lord Lonsdale, to a point near Clifton below Askham, and at that point there will be a waste weir, and at that waste weir another conduit will be made to conduct a certain portion of all those waters into Ulleswater near Pooley Bridge.

351. (*Sir J. Thwaites.*) How far are you opposite the castle from the beck?—I suppose it would be about a mile and a half below the castle. All the waters that are required for compensation to the river Lowther would pass over this gauge weir, and would continue to flow down the river Lowther. That would be 28 inches, or whatever the amount may be which I alluded to before as compensation water, which would run away as before into the river Lowther.

352. (*Chairman.*) You stated that you raise Haweswater 42 feet, do you mean the depths of the water, or the banks, or what?—42 feet will be the additional height of the water in the lake as compared with its present surface.

353. (*Mr. Harrison.*) With an embankment across the mouth of it?—Yes. The surface of the lake would be 42 feet higher than it was before.

354. (*Chairman.*) How do you propose to confine the waters within that Haweswater Lake?—We propose to make a short embankment across the gorge—Haweswater is a very narrow lake—and at the end of it, where the Haweswater River runs out, there is a narrow gorge some 300 feet wide, across which we make an embankment 42 feet high to confine this water.

355. (*Sir J. Thwaites.*) What will you do with all those little farms at the side of the water up towards Mardale?—The farm property that we take is very small, and some as you see will not be touched at all by the raising of the embankment. But Mr. Hassard will give the details of the arrangements with regard to this, and he will state what quantity those amount to.

356. (*Chairman.*) It will be merely necessary to place an embankment over the gorge 300 feet across, and an embankment 42 feet high would confine within Haweswater the additional amount of water that you put into it?—Yes.

357. That is to say, the sides of the lake are so precipitous on three sides that they do not require any more embanking?—Just so, it is simply by placing an embankment across the gorge. I forgot to state that having done that, Haweswater will contain 1,196,000,000 cubic feet, and the drainage of 38 square miles by those catchment conduits.

358. (*Sir J. Thwaites.*) That is a provision to compensate the river Lowther also, is it not?—It is for both purposes. Part will run down the river Lowther as before, and a part will follow the line marked on the map from Clifton to Pooley Bridge, and be discharged into Ulleswater.

359. What is the daily additional water that you would permit to flow over into the river Lowther?—It would be the whole excess, whatever the level is at the time above the 36½ inches that we want.

360. When it masters your storing power of course it will flow over; but I am speaking now of the dry weather discharge?—In dry weather, if we take 48 inches, the discharge is the difference between the loss of what we take and that 48 inches; and if the dry-weather fall is only 60 or 61 inches there will be about 12 inches to go off. I think that Professor Symons

makes the dry-weather rainfall 62 inches, but I am not quite certain. Whatever that is it is the difference between that and 48½ inches which will go then to the compensation.

361. Will you in dry weather diminish or increase the quantity of water flowing down the river Lowther?—In dry weather we shall increase the quantity of water flowing down the river Lowther.

362. You mean that you will equalize it?—Yes, we shall equalize it; because, as you will observe, we have stored it up in Haweswater, and we should give it them when they would not have it from the skies. Before going to Ulleswater I will go on to the Thirlmere gathering ground. At the point called the Barrow Beck we make a conduit which follows the red line on the map, and takes up the Mosedale Beck and keeps running round the gathering ground by the High Fells, and discharges all the water that falls on Matterdale Common into Thirlmere. We then go south, and there is a wet district of 6 square miles, which is gathered by two conduits; and having been collected at the point which you see marked on the map, instead of going to Ambleside southwards, all that water is thrown back by a tunnel into Thirlmere. And Thirlmere is raised 64 feet by an embankment at the north end in a similar manner to what I described at Haweswater. At Cold Barrow Fell another of those catchwater conduits is made passing by Wyth Burn and by Bleaberry Fell with a branch out towards Keswick, and all those waters are collected and carried to the north end of Thirlmere also, and then Thirlmere will contain 1,722,000,000 cubic feet.

363. (*Col. Harness.*) Do you propose to give any compensation to those streams which have been turned from the south to Thirlmere?—No, we have not considered it necessary to propose any compensation for that; it is a small stream, without any mills or works upon it; but that might be done if it is discovered to be necessary.

364. (*Sir J. Thwaites.*) Before it comes to an important stream there are some tributaries to it, are there not?—Yes, there are some tributaries and there is a gathering ground still left upon it, so that it might not be necessary to provide for compensation.

365. You propose, do you not, to raise Thirlmere 64 feet?—Yes.

366. At the end is it not very narrow?—Yes, quite a gorge.

367. How do you propose to deal with the road close to the lake?—The road will have to be raised to the margin of the new lake.

368. How will you get the road up to 64 feet?—The whole of that road rises most rapidly as you get towards Ambleside, and that country it rises very considerably. You go up a very steep hill for a great way, and if we make a gradual incline along the margin of the lake we shall improve the road.

369. You will have to remove several houses, will you not?—There are some houses to be removed. Mr. Hassard will give the details of that. I have been all along the route, but I have not got a list of the houses myself. Then it is proposed that there should be also a gauge at the north end of Thirlmere. A portion of the compensation water will be let off there and accumulate in a reservoir on what is called the St. John's Beck, and that will be used for a compensating water reservoir for the Greta River, upon which there are some small mills near Keswick.

370. (*Chairman.*) What is to be the size of that reservoir?—That reservoir is to contain 380,000,000 cubic feet.

371. (*Sir J. Thwaites.*) Is that the discharging capacity or the holding capacity?—That is the holding capacity.

372. What is the discharging capacity?—The discharging capacity must be the surplus that that will give us.

373. Can you discharge to a certain depth?—I cannot give you that; but any details of that kind Mr. Hassard has worked up and will give the Commissioners. I do not remember at this moment what the discharging level of that reservoir is. Then we have collected the waters in that district of 44 square miles into Thirlmere, which will now be conveyed by an outlet conduit and tunnel into Ulleswater. That line of conduit runs from the north end of Thirlmere round by Matterdale Beck and Dacre Beck, and discharges into the north end of Ulleswater.

374. Do you tunnel through the whole of it?—Yes, we tunnel through the whole of that dotted part.

375. Is not it limestone in that district?—No, it is all Silurian ground. We have no limestone in the district.

376. (*Mr. Prestwich.*) What scale is that map on the wall?—6 inches to the mile.

377. (*Chairman.*) What is the length of the tunnel through Matterdale?—That tunnel would be seven miles, but it is a shallow tunnel, and it is merely dependent upon the number of shafts. There is no difficulty in a shallow tunnel. The deepest shaft would be 400 feet. We have now got the 38 square miles of Haweswater, and the 44 square miles of Thirlmere delivered into Ulleswater.

378. As I understand you first of all, you take the drainage of 44 square miles and put it into Thirlmere first, and then you take it out again?—Yes, in order to bring it to Ulleswater, which is our supply reservoir. The other two are only to maintain the level of Ulleswater. Ulleswater itself is to be what may be called the London reservoir. The others are only to keep it supplied, the great object of that being to avoid, as much as possible, the alteration of the level of Ulleswater, which is a romantic and beautiful lake. Those other two are lakes not frequented; they are without hotels and accommodation, or any particular beauty about them. They are not those lakes that people frequent, and therefore altering their levels is of no consequence in a scenic point of view, which would not be the case with regard to Ulleswater, because it is a very beautiful lake, and the object there is to keep the level even as much as we can. It will be observed that the natural drainage of all these lakes is northward, but we would propose having stored all this water in Ulleswater to take it southward. Ulleswater itself possesses a gathering area of 95 square miles, and it could be raised five feet above its average winter level, and would then contain 1,742,000,000 cubic feet.

379. (*Col. Harness.*) To what extent do you propose to consider it available?—Twelve feet below its present level.

380. (*Sir J. Thwaites.*) You will tap it to that depth?—Yes.

381. That will be seven feet below the present level?—No, we raise it five feet and take 17 from it, and that leaves 12 below the present level.

382. Can you raise it five feet without interfering with the houses which are on the lake?—Yes. By making a very slight embankment at the south end, and throwing the drainage of all the Patterdale district into one tunnel, we can protect that portion entirely. It will have no ugly appearance, nor will it injure or flood the property at all.

383. Take Mr. Marshall's house for example, will not five feet carry the water into his ground?—No, not if we bank it out.

384. But you will put his property below the level of the lake water?—No. I think that five feet will not put it below the level of the lake water. I think it will still be above the lake. There are some meadows close to the lake which five feet will cover, and which I believe are sometimes covered in a high winter flood now; but we should keep them dry by an embankment.

385. (*Chairman.*) What would be the height of the embankment which you propose to put at the south end?—It would raise the water five feet, but the embankment itself might be seven or eight feet high.

G. W. Hemans, Esq.

13 Feb. 1867.

386. Would that be the winter level of the water?—I imagine that the winter level of the water would be very nearly that in very wet seasons, but perhaps not quite so much.

387. Then you propose to add to that, do you not?—No, to add to the average winter level, not to the extreme winter level. The extreme winter level at present, in Ulleswater, sometimes covers the road from Patterdale.

388. You propose to add five feet to the average winter level, but when the lake rises to what is not the average but an extraordinary winter level, what will happen?—I do not think that we shall make it much worse than it was before, because we shall never exceed the five feet above the average winter level. We shall not increase it, for if more water comes down we shall not use it, but we shall pass it away by this culvert.

389. When you propose to raise it five feet above the average winter level, you mean that you will put five feet more water than the average winter level?—Yes.

390. Then when the water is at an extraordinary winter level, you would be five feet over and above that again, would you not?—No, certainly not, because we should not allow the water to go in. We should be much more likely to make the lake more secure in winter than it is now.

391. How will you do that?—Because we shall regulate it by putting a weir at Clifton. We shall prevent any additional water going in by passing it down the river Lowther, if we find it going above the level which we maintain, and which we mean to be permanent, that is to say, when we are not in drought.

392. (*Sir J. Thwaites.*) You will have a strong overflow at that point?—Yes, and we shall do the same at Thirlmere.

393. (*Chairman.*) What you mean is, that the lake will never be more than five feet above the average winter level?—No, we profess that we can maintain it rigidly at that level, except when it has to be lower than that. When there is a drought we may have to lower it, but it will never rise above that. We draw off the water at the southern end, and we prevent its entrance at the northern end, so that we have power to regulate it absolutely.

394. (*Sir J. Thwaites.*) Have you ascertained to what height the floods in the winter will raise the lake?—Vaguely. Local information about floods is always rather vague, but we ascertained that very high floods frequently covered the high road to Patterdale.

395. Have you observed upon the upper part of the lake, on the opposite side, a rock upon which the heights of the floods have been marked?—Yes. I do not recollect observing the exact height, but I did see the rock. I think Mr. Hassard may be able to give that information.

396. If you give an increase of five feet, will you not flood the district when the floods are more than the ordinary winter floods?—Yes, but I was explaining that we cannot flood the district if we bank it up, and we shall protect it by an embankment at the south end of the lake.

397. You propose to raise the level five feet. That will increase the quantity of water, and will not, therefore, the quantity of water in the winter floods, which you cannot pass, be increased by your embankment?—Our embankment and our means of drawing and regulating both the outlet and inlet will make it impossible for those floods to rise; we can regulate those floods absolutely.

398. (*Mr. Harrison.*) If I understand you, the main embankment will be at the northern end, at Pooley Bridge, and the embankment to which you are referring, at the south end, will be simply for the purpose of protecting some low grounds?—Yes, simply for that purpose. The embankment to the north is a very slight affair. There is already a ridge there with only an opening for the river to pass through, and at the south end the object would simply be to protect the Patterdale meadows, and prevent the five feet from running into those grounds.

399. (*Sir J. Thwaites.*) How will the inn at Pooley Bridge be affected?—The inn at Pooley Bridge is below our banks. There is a bridge there, and the inn is below that bridge; we shall not encroach upon the inn at all. Then our plan is to reverse the drainage towards London instead of allowing it to flow northwards as it does at present, and for that purpose we have to make a long tunnel under Kirkstone Pass. The total length of that deep rock cutting will be more than seven miles, and of that seven miles five miles will be in tunnel, and out of the five miles one and three-quarter miles will be incapable of having shafts sunk, on account of the great height of the mountain above, and therefore that becomes the measure of the work.

400. That is the highest part of England, is it not?—I am not aware whether it is the highest pass in England, but it is a very lofty pass, and the height of the pass will preclude the sinking of the shafts in a mile and three-quarters out of that five miles of tunnel. That, then, becomes the measure of the work in point of time. The size of the tunnel will be 20 feet by 15 feet, and I may as well mention that among the many works which I have constructed I have within the last few years made a long tunnel in Silurian slate of the same description in one of my railways in Ireland, about a mile in length, and I am well acquainted with that rock and the rate at which it can be worked, and, although the tunnel which I constructed was not done with anything like the rapidity with which we should propose to construct this, I am able to say from experience of the Mont Cenis tunnel, that if we proceed at the rate at which they have been able to do, we should complete that mile and three-quarters in three years.

401. (*Chairman.*) Could you give us the rate at which they have been able to work in the Mont Cenis case?—We will put in a table showing the rate at which they have been able to work.

402. (*Sir J. Thwaites.*) You will only have two faces, and in the Mont Cenis tunnel they bore at the rate of a yard and a half a day at each face on the average, I believe?—Yes, about a yard and a half a day. They use very beautiful machinery there for drilling holes, and they get on in a way which I never saw done in tunnelling before.

403. When you come out of the tunnel at Ambleside you approach Lake Windermere, do you not?—Yes. I propose, if the Commission will allow me, to leave the description of the aqueduct and some other matters connected with the business to Mr. Hassard, who has worked up a great many more details than I have, and will be able to give them better. I think I have given every description about the lakes. I might observe here that Professor Way's analysis of the water is given in my pamphlet.

404. (*Chairman.*) You propose that Professor Way should be examined, do you not?—I am not certain that he will be able to appear; he is out of London at present, but if he returns it will be better that he should be examined. I can send in his original letter to me with his analysis in it, and then he can be examined upon it at length. He gives a most favourable account of the water, as being the very best for the purpose.

405. Can you give the Commission any evidence with regard to the existence of any lead mines in the neighbourhood of Ulleswater?—Yes, there is a lead mine on Glenridding Beck, which at present discharges itself into the stream which runs into Ulleswater. There is no lead in that stream, I believe, but there is all the foul washing of the matrix in which the lead is found, and that gives round the mouth of the stream a very ugly appearance to the water; but there are many ways of dealing with that. We can lead that water away either round the lake

in a pipe, because a moderate pipe will take that foul water, or we can take it in a pipe along our own tunnel, or we may use settling ponds and let that foul water settle.

406. Supposing that you carried that foul water by a tunnel or pipe round the lake, would not that reduce the quantity of water that there would be in the lake? —Not to any extent worth mentioning. We think that an 18-inch pipe would take all the water necessary for washing the ores. At present it looks very formidable, because they simply turn their foul washing into the pure water, and this comes into the lake, and all the river water is foul.

407. Do you propose, when you say that you will carry it by a pipe round the lake, to divert that large river?—No, only the portion of water that is necessary for the washing of the ores.

408. (*Sir J. Thwaites.*) I presume that Professor Way can give us his opinion as to the effect of that colouring matter on health?—No doubt; but I think the best manner to treat that will be in the first place to use several settling ponds, and we should probably deliver that water after passing through them clear into the lake, but if there remained still a trace of lead of any kind we should then have to pipe it away.

409. Where is the lead through which this water goes for washing the ore?—The washing takes place at the mills on the stream, on the spot.

410. (*Mr. Prestwich.*) What distance up the stream? —I think it is about three miles up the stream. There is another not quite so extensive mine on the other side of the ridge of Helvellyn, which delivers water into Thirlmere, which would be treated in the same way, either by piping it away to some of our outlets, or else by settling ponds; but I think it will be found that there is little or no lead in that washing, but merely the clay which the lead is in.

411. (*Sir J. Thwaites.*) Still it discolours the upper part of the lake?—Yes, and people who pass it without any knowledge think that it is all lead and all poison, but I may observe that the favourite spot for fishing is just round the mouth of that river; the fish seem to find something in that clay which they like, because it is there that people fish, and I do not believe that there is anything really injurious in that water.

412. (*Mr. Harrison.*) What is the probability of other lead mines in future years being opened out in that district?—That is a question which I am afraid I am not able to give any very satisfactory answer to that is worth much, but it is my opinion that if a reservoir like this should be made for the supply of London, no lead mines ought to be allowed in that district.

413. Would not the owners of those mines be entitled to claim compensation at once for that?—It is very doubtful whether they would be entitled to claim compensation considering that they have no right as I think to foul by their washings any water used by the public. If it should turn out, as I think it very probable it may, that those washings can be conducted without in the least fouling the water of the lake, there is an end of the case, but if not it seems to me very doubtful what right any parties can have to put up works to foul a supply of pure water to the public.

414. (*Chairman.*) Is there any other point upon which you wish to give evidence?—I find, as I think Mr. Bateman did, that an average rate of 10*d.* in the pound with the sale of water on the way would amply cover the interest on the amount of money required and the expenses of doing the work.

415. It is rather vague to speak of a 10*d.* rate and the sale of water on the way, ought you not rather to tell us what towns you propose to supply, and the cost of supplying each of those towns?—I am afraid that I cannot state precisely the towns that we are going to deal with, because we should have to communicate with them. We assume 50,000,000 gallons a day for the supply of other towns.

416. (*Sir J. Thwaites.*) You state that that 10*d.* rate which you propose to charge is after deducting the price which you receive for the water that you distribute on the way?—Yes.

417. But you cannot say how much you will receive for water distributed short of the metropolis?—I will give that. We assume a sale of 50,000,000 gallons, but we are not able to say where it will be distributed, but it will be somewhere on the way. It is not much to assume that 50,000,000 gallons of water a day in those populous districts will be readily taken at 3*d.* per 1,000 gallons which is a very moderate price. That would give an income of 228,125*l.* per annum, and we estimate the cost of the whole of our works at 13,500,000*l.* which at four per cent. would require 540,000*l.* per annum, and we assume that the cost of collection would be 100,000*l.* per annum, and that the dividends to the water companies would be 425,000*l.* per annum, making a total annual charge of 1,065,000*l.*

418. (*Sir B. Phillips.*) But you take this 10*d.* rate, do you not, on a gross valuation of 20,000,000*l.*?— Yes, it being between 15,000,000*l.* and 16,000,000*l.* now.

419. The present valuation, I believe, is only 15,500,000*l.*?—I think it is nearly 16,000,000*l.*, but we are assuming an increase of demand at a less rate than it is now proceeding at.

420. (*Sir J. Thwaites.*) Are you of opinion that the works will take four or five years to complete?— Yes. When we talk of four or five years from the present time, I should say there may not be much probability that the power could be obtained and everything settled in less than ten years from the present day, or in eight or nine years at all events, so that I think it is not too much to expect that the valuation would be 20,000,000*l.* Then 20,000,000*l.* would give 833,333*l.* a year at 10*d.*; the sale of the water on the way would give 228,125*l.* as I stated before, and the sale for trades purposes, if the amount is at all in the same proportion as in other towns, would amount to 250,000*l.* a year, making a total of 1,311,458*l.* per annum, and showing a very large surplus over the annual charges.

421. (*Chairman.*) Then are we to understand that Mr. Hassard will give reasons for supposing that the rainfall in the Welsh district is not sufficient?—Yes; we consider that the observations in the Welsh districts have not been at all sufficiently long; they have been only during three months in the district in question, and those were three very wet months, and they are hardly sufficient to go upon for the rainfall.

422. (*Mr. Harrison.*) Mr. Bateman stated that they were not wet months in that particular district?—We have compared the rainfall in those three months from the table of the rainfalls all over the country, and we find that those three months in almost every district were nearly half the whole rainfall of the year. I have here a sheet published by Mr. Fletcher, of the rainfall in Cumberland and Westmoreland, in which you find that at every station almost the rainfall during those three months was nearly half the rainfall of the whole year.

423. (*Chairman.*) Taking that particular district in Wales, was it so?—That I am not able to say. If Mr. Bateman says it is not so, his evidence is worth more than mine, because I do not know it.

424. (*Mr. Harrison.*) In the north of England we have had an enormous rainfall when in several parts of the south-east of England it has been comparatively small; might not that be the case in Wales? —I cannot give you information upon that. Mr. Bateman knows that better than I do.

425. (*Chairman.*) You wish us to understand that you will not contradict Mr. Bateman?—Precisely so.

426. (*Sir J. Thwaites.*) But am I to understand you to make this statement, that the gauging in question was simply during three months?—Yes,

G. W. Hemans, Esq.
13 Feb. 1867.

that is as I understood Mr. Bateman's evidence, that the district had only been gauged during three months.

427. And that during those three months there was a very heavy fall of rain?—It was unquestionably very wet in many parts of England, and my decided opinion is that three months gauging is entirely inadequate to enable one to decide upon a question of this great importance.

428. (*Chairman.*) You are not prepared to say whether or not it was an excessive rainfall or the reverse in that particular district?—No, I cannot state that. I can state that in the north it was an excessive rainfall, equal to half the rainfall of the whole year. I may perhaps observe that we propose using in part of our works instead of cast-iron pipes wrought-iron pipes of great diameter, which we think will be a great economy, and we want to show that by rendering it inside with Portland cement, that kind of pipe will have no danger whatever of oxidation. We have brought a sample of the pipe, which we should be very much obliged if the Commission would look at.

429. (*Sir J. Thwaites.*) Will the cement stand?—It can all be done as that sample is, and you will not have the slightest doubt of its standing. Portland cement is improving immensely every year in its manufacture, and we believe that it will be an admirable way of doing it; the rendering is half an inch thick that we put in, and if you can have an eight foot pipe of wrought iron you will greatly improve the working, because it will admit of much greater velocity of current. It is a great advantage to have pipes in wrought iron, which can be made so much lighter and so much less weight to carry.

430. (*Mr. Harrison.*) Your proposed mode of conducting the water in your conduit differs from that of Mr. Bateman from the fact of the greater distance that you have to traverse obliging you to adopt a greater fall per mile, and consequently all your works must be of greater magnitude and larger sectional area?—Yes, they must be of larger sectional area, but our mode gives us a more economical construction, because the slower the velocity the less chance there is of injury by the current of water.

431. Mr. Bateman, in his evidence, states that excepting where he goes through stone, he proposes to line his conduit from end to end with brick, and that by so doing he can adopt any velocity that he likes; do you agree with him with regard to that?—No doubt he can do so.

432. You propose to make yours a river flowing slowly, and you assume that where you pass through particular soils you may avoid the lining, although is is even through clay?—We propose to line it all the way, but not in an expensive manner, merely with the rock of the district and with hydraulic lime.

433. Do you propose to line it the whole way?—Yes, it will probably be necessary to line it the whole way. In fact it is a question of height and distance. The height of Mr. Bateman's plan is very nearly the same as ours, but our distance is longer than his, and therefore we make a rather larger conduit, but we do not make it quite so expensive.

The witness withdrew.

Adjourned to to-morrow at 11 o'clock.

Thursday, 14th February 1867.

PRESENT:

His Grace THE DUKE OF RICHMOND in the Chair.

Sir John Thwaites.
Colonel Harness.
Alderman Sir Benjamin Phillips.
Thomas Elliot Harrison, Esq.
Joseph Prestwich, Esq.

George James Symons, Esq., examined.

G. J. Symons, Esq.
14 Feb. 1867.

434. (*Chairman.*) You are a Fellow are you not of the Meteorological Society?—Yes.

435. And editor of the "British Rainfall?"—Yes.

436. And secretary to the Rainfall Committee of the British Association?—I am.

437. Have you for many years past devoted the whole of your time to the collection, classification, and discussion of the rainfall returns from all parts of the British Islands?—For many years.

438. And in different parts of the country have you upwards of 1,500 gauges at work?—I have; that is to say, returns are forwarded to me from those places, and many of the gauges are my own.

439. Are you acquainted with the whole of the Lake district?—I have walked over a great portion of it repeatedly, especially the eastern portion.

440. And amongst other things for the purpose of meteorological observations?—Precisely so.

441. Have you prepared an analysis of the observations which you have made bearing on the rainfall of that district?—I have prepared an analysis of every return which has been procured from any part of that district, and I have the pleasure of handing it in. (*The witness delivered in the following paper.*)

Report on the Rainfall of Parts of Cumberland and Westmoreland, by G. J. Symons, F.M.S.

The unusually complete evidence (that of 22 years, and for the whole or part of that time of 30 rain gauges) as to the rainfall in the district proposed to be taken up by Messrs. Hemans and Hassard, may be divided into two portions: 1. Discussion of old observations in and closely adjacent to the district; 2. Discussion of the results of gauges recently erected at other places within the district.

As to the first point it may be well to state (to prove, if desired) that the simple arithmetical mean of the rainfall at any place is a fallacious guide to the true mean rainfall unless it is based on a long series of years. The only mode by which observations continued only for a few months or years can be made available is by first establishing the ratio of the rainfall in those months or years to the mean of a series of years. This has been done in Table I., wherein the total rainfall in each of 22 years at three stations close to the district under consideration (in fact a triangle joining them would include much of the district) has been reduced to ratios showing at once the relation of each year to the average. The mean of the ratios of any year at the three stations has been held to indicate the true ratio of the fall in that year to the mean of the whole period of 22 years. Table II. contains *every* record of rainfall in my possession affecting the question at issue, the stations being arranged

in the order in which they are printed in my report to the British Association (1865, pages 208, 209, and 225).

The means have been taken both arithmetically, in the ordinary manner, and also reduced by the method already indicated to the true mean of 22 years.

I believe this second line of figures (those quoted on the map) shows the lowest possible mean fall at the places named. I am quite certain the errors are in defect rather than in excess, and may perhaps be permitted to point out reasons for this statement.

(1.) No correction has been applied for the elevation of the mouth of the gauges above the ground, which materially diminishes the amount collected.

(2.) No correction has been applied for errors in the gauges themselves, yet these are possibly, I might say probably, considerable. To take two instances only, Greystoke and Hallsteads. At the former the instrument is of the pattern known as Crosley's patent rain gauge, a clockwork contrivance, which meteorologists have long rejected for its errors; at Hallsteads the gauge is similar to the one at Crow Park, Keswick, which, by reference to the tables, will be seen to record about 14 per cent. too little. This would raise the fall at Hallsteads to 61 inches.

(3.) Several of the years forming the 22 years' average, adopted as the standard of reference, were exceptionally, if not unprecedentedly, dry, and I may add that I have previously shown (British Association Report, 1865, p. 203) that the years in question are far below the average of the 50 years 1815 to 1864.

I believe that these three sources of diminution may be approximately taken at 10 per cent., and that at the comparatively dry spots (therefore selected as residences), where observations have been made for many years, good gauges, well placed and properly attended to, would show a fall at least one-tenth greater than that shown on the map.

I may here appropriately offer a few remarks on droughts in the Lake district. Those at Seathwaite in ten years ending 1859 were—

						inches.
1852	-	Feb. 18	to April 28	-	69 days	- 1·06
1854	-	April 1	to April 26	-	25 „	- 0·70
1855	-	Nov. 13	to Dec. 22	-	39 „	- 1·40
1857	-	June 12	to June 28	-	16 „	- 0·00
1858	-	Feb. 14	to March 4	-	18 „	- 0·00
1858	-	Oct. 28	to Nov. 24	-	27 „	- 0·13
1859	-	June 29	to July 19	-	20 „	- 0·00

There was therefore only one drought of more than 40 days and more than an inch of rain fell during its continuance.

Further information is afforded by the subjoined table, which shows the rainfall in the two driest consecutive months at each of the undermentioned stations:—

1852. March and April.		1861. April and May.	
Stye Head - -	1·64	Mire House - -	2·37
Lesketh Howe -	1·14	Low Nook - -	2·45
Selside - - -	1·49	Grasmere - -	2·33
Stonethwaite - -	1·41	Lough Rigg - -	2·35
The Stye - - -	1·78	Lancregg - -	2·83
The Howe - -	1·22	Patterdale - -	·72
Keswick - -	·94	Hallsteads - -	0·00
Seathwaite - -	1·72	Watermilloch -	2·50
Penrith - - -	1·03		

Hence we see there is only one instance of two months without rain, and that is unsupported by the returns from the nearest station. Moreover, it will be noticed that these droughts—the only ones on record in the district—occurred in the two years remarkable for the largest yearly totals.

G. J. Symons, Esq.

14 Feb. 1867.

TABLE III.

The second portion of evidence is that from gauges erected in September 1866. The following table gives the results to January 1, 1867.

Position.	Height of Gauge. Above ground.	Height of Gauge. Above Sea level.	October.	November.	December.	Three Months.
	Ft. In.					
Watendlath - -	1 0	867	6·50	11·25	15·13	32·88
Wythburn Parsonage -	1 0	574	5·88	12·88	17·25	36·01
Helvellyn Birkside -	1 0	1,800	5·75	12·00	14·50	32·25
Matterdale - -	1 0	1,400	5·25	7·75	18·75	31·75
Gowbarrow - -	1 0	1,100	4·33	7·25	17·25	28·83
Greenside Stang End -	1 6	1,550	4·64	10·44	11·70	26·78
Do. Mills -	1 0	1,000	6·74	12·99	17·45	37·18
Swarth Fell - -	1 0	1,000	3·50	5·50	7·00	16·00
Measand Becks -	1 0	1,200	3·50	4·50	7·50	15·50
Mardale Green - -	1 0	800	3·75	12·25	16·50	32·50
Wet Sleddale - -	1 0	1,500	7·75	10·50	15·75	34·00
Kirkstone Pass -	1 0	1,500	7·25	12·00	13·50	32·75
Easedale Tarn - -	1 0	1,175	7·50	14·25	18·25	40·00
Average - -	1 0	1,190	5·57	10·27	14·65	30·49

The rainfall in the three months October, November, December, in mountain regions is very nearly 30 per cent. of the total yearly fall. If this rough, but convenient rule, were applied to the preceding observations, they would give for the district a mean annual rainfall of 100 inches. But, in spite of the dryness of October, it might be argued that they were three wet months. I purpose to ascertain from the records of the old established stations, exactly the real per centage of these identical three months, so that there can be no possibility of doubt.

RAINFALL, October to December 1866, at the undermentioned stations, compared with the average at those stations.

——	Oct.-Dec. 1866.	Average from Tables I. & II.	Percentage in Oct.-Dec. 1866.
Scathwaite - -	58·09	140·03	41
Ambleside - -	29·17	76·86	38
Keswick - -	21·82	58·53	37
Patterdale - -	28·62	74·72	38
Hallsteads - -	15·40	52·44	29
Watermillock -	18·00	54·66	33
Great Strickland -	10·84	38·62	28
Average - - -			35

We thus find that the real average was 35 per cent., about 40 per cent. at the western stations and 30 at the eastern. Applying this determination to the data in Table III. we deduce the true mean fall at each of the new stations to be as follows:

Watendlath	82 inches.	Swarthfell	53 inches.
Wythburn	90 „	Measandbecks	52 „
Birkside	81 „	Mardale Green	108 „
Matterdale	80 „	Wet Sleddale	113 „
Gowbarrow	72 „	Kirkstone Pass	82 „
Stang End	67 „	Easedale Tarn	100 „
Greenside Mills	93 „		

Mean of these 13 stations = 82 inches.

Taking the divisions of the six inch ordnance maps as subdividing the district into areas, for each of which the rainfall may be separately determined, I believe the following values are rather below the average fall in each:

Cumberland, sheet	LVII.	= 60	inches.
„ „	LVIII.	= 45	„
„ „	LXV.	= 80	„
„ „	LXVI.	= 53	„
„ „	LXX.	= 93	„
„ „	LXXI.	= 85	„
„ „	LXXV.	= 100	„
Westmoreland, „	XVIII.	= 100	„
„ „	XIX	= 90	„
„ „	XX.	= 100	„
„ „	XXI.	= 85	„
„ „	XII.	= 80	„
„ „	XIII.	= 65	„
„ „	VII.	= 45	„

True mean rainfall for the district 77 inches.

Mean of three dry years (80 per cent. of mean) 61·6 inches.

G. J. SYMONS.

136 Camden Road, N.W.

P.S.—The returns for January 1867 indicate a higher mean at the new stations than that of 82 inches herein deduced from previous months.—G. J. S.

442. What is your opinion of the quantity of rain which can be permanently reckoned upon in that district?—At the very least 77 inches.

443. (*Sir J. Thwaites.*) Are you referring to the lake district?—Yes, I am, and on this map, which I will now put in, I have marked the exact fall at each of the places (*handing in the same. See Map, Appendix* F. (1.)) You will perceive that some of the stations are underlined with a red stroke, those gauges have not been at work for so long a period as the others.

444. Are those Dr. Miller's—Portions are Dr. Miller's, which have been renewed, as you are no doubt aware, by Mr. Fletcher, but Dr. Miller's observations are almost exclusively confined to Langdale and Borrowdale, the other portions are comparatively untouched, except that we have some very old gauges in dry spots in different places round about Ulleswater—there is one by Mr. Marshall, the member for Cumberland.

445. (*Chairman.*) How long have those gauges been in operation?—The short period ones have been in operation three months. I may add that the January returns have since come in, and they indicate rather higher values than those marked upon the map, which map was prepared before the January returns came in.

446. But those figures under which you have placed the red line represent gauges which have been down for three months?—Yes.

447. And the gauges in the other parts of the district have been down for how long?—In some cases 22 years.

448. In how many cases have they been down 22 years?—The gauge at the Howe Trout Beck at Windermere has been down 22 years with a mean of 80 inches, and the Seathwaite gauge has been at work 22 years. There can be no doubt whatever about that.

449. Will you give us seriatim the numbers which are on this map, and the number of years which each gauge has been down (I assume that each number represents a gauge), commencing with number 80, which has been down 22 years?—Those numbers represent the absolute fall at those spots, and not the number of the station, that is to say, there is no reference number to the station. The rainfall is 80 inches, or whatever the number of inches are marked on the map.

450. But then, although each number represents the inches there, it also represents the gauge?—Yes, certainly.

451. The one marked 80 at Trout Beck has been down you say 22 years?—Yes, and the Seathwaite gauge, marked 140 inches, has also been down 22 years, and the Keswick gauge, marked 59 inches, has been down 22 years. I have a table which shows the number of years and the fall each year.

452. Therefore at Trout Beck, Scathwaite, and at Keswick, the gauges have been down 22 years?—Yes, and the yearly falls at all the other places are given on the large sheet, and where there are blanks there are no returns. Perhaps I might be allowed to make one remark as to the principle upon which that table has been constructed; it is this, the mean of a few years, or of a short period of observation, is no true guide to the real mean of a large number of years. They may be four or five wet years or four or five dry years, and it would not do simply to compare the mean of those years irrespective of their relation to the mean of a long period. It is consequently necessary to establish some kind of standard of reference, so that we shall know whether an observation made, we will say in the year 1845, represented an average year, whether it was a wet year or whether it was a dry year. If we have not the means of doing that we cannot reduce it to a real indication of the average, and therefore the three stations of Trout Beck, Seathwaite, and Keswick, where the long observations have been continued, were reduced to ratios or percentages, and those percentages have been multiplied into the fall in any group of years anywhere else, so as

to reduce them to their true value, consequently I get two lines of means at the foot of this table, one of those lines of means being the arithmetical means which can be taken if the other be not possible, but I should say that it is preferable to take the true mean, which is computed in the way I have described. That is the only remark which I wish to offer upon that table.

453. (*Sir J. Thwaites.*) Is that line which you have marked the gauging area of Mr. Heman's scheme ?—Yes.

454. And why is there the distinction of a red boundary ?—I believe that that is a second portion which they propose to take up, but I have nothing to do with the engineering department.

455. (*Mr. Prestwich.*) Are you able to divide the rainfall into seasons ?—They have simply taken the gross fall ; at the same time, in working out the three months last year, during which the new gauges have been established, I have reduced them to their true values by determining the ratio of the fall in those months at old established stations to the mean at those old stations.

456. Can you not give us the divisions into seasons ?—I could prepare it in that way, but I have not the materials with me at present. I should be most happy to prepare it, if desired. I may add roughly, that the percentage of the total fall which usually falls in the three months of October, November, and December is 30 per cent. of the total, or nearly one-third falls in those three months.

457. In Mr. Heman's pamphlet a table is given of the number of days on which rain falls, as computed by Mr. Beardmore ; have you prepared also similar tables ?—I have not, because I believe there is no more fallacious and no more difficult thing than to find the number of rainy days, or what is called a rainy day. That has been a source of discussion in my own periodicals for some years, and it is only during the last two years that any decision has been come to. We now always count not as a rainy day but as a day with rain, a day on which not less than $\frac{1}{100}$th of an inch falls ; it is simply in order to get some uniform standard.

458. Would not the amount of evaporation in a number of days in which rain falls be a very important consideration ?—It would, but in a district like the lakes, where the rocks are so very hard, I imagine that the water runs off very rapidly ; in fact, I know from my own personal knowledge, that it is all down into the lakes almost instantly, and consequently the evaporation from the surface of the ground, in the ordinary sense of evaporation or percolation, is almost nil. I might illustrate that by referring to the notoriously wet districts of Seathwaite and the Stye. The Stye had 224 inches of rainfall last year. I was at Borrowdale in October of last year, and I found that during the previous month of September there had been, I think, 32 inches of rain. I was close to the Stye again, and all about the valley, in the subsequent month, on the 14th of October, and the brook was entirely dry, there was not a trace of water to be seen, it had all rushed down into the Derwent Beck and escaped, just illustrating how instantaneously the water escaped, and showing that the rains of September had no effect at all.

459. There is no doubt that, with a hard rock like that in this neighbourhood, very little passes into the surface of the ground ; therefore, unless it ran off rapidly it would rather favour the evaporation from the surface, and if there was any cause to retain it on the surface to prevent its more rapid flow the evaporation would be all the greater ?—Yes.

460. And as that district is covered by thin vegetation, especially heath, would it not be extremely retentive of water, and would not it be likely to produce considerable evaporation, and yet at the same time it would be very difficult to determine the amount of evaporation, or is it possible to determine the amount of evaporation ?—I am inclined to think it is impossible, except by experience in analogous cases, and how far that may be forthcoming I do not know ; it is a question which I should like to take up, but the rainfall takes up all my time, and I have not time to go into that matter ; but my own impression and experience from travelling over the ground is that it is very soon dry. There are no doubt patches here and there in which the substratum is somewhat cup-shaped, and there the water must stand and keep it wet, but looking to the general inclination of the ground, which is very steep, I am disinclined to think that any considerable quantity can be retained.

461. Have you paid sufficient attention to that subject to form any probable idea of the relative proportion of rainfall which may be removed by evaporation, assuming the quantity there to be, as you say, 77 inches ?—I should not like to speak with equal confidence with respect to that as with respect to the rainfall ; but speaking from my general reading upon the subject, and not from any careful and accurate inquiry, my impression would be that about 10 or 11 inches would be the amount to be deducted ; but that, as I said before, I merely give just *quantum valeat.*

462. And that has often happened from a small fall ?—Yes. In the case of the Belfast waterworks I believe the decrease was found to be about 13 inches, and if you were to double that it would give us 26 inches, but the ground being entirely different I assume a very different value.

463. So that it depends upon a variety of conditions and without direct experiments it would be almost impossible to come to a direct conclusion ?—Yes, and direct experiment I believe to be almost equally impossible, except by impounding the water, that is to say, by gauging the rivers ; and those rivers are almost impossible to gauge, they come down so violently. I should like to be allowed to add a few words on the duration of droughts. With respect to droughts at Seathwaite I find that the only drought during the 10 years ending 1859 was one of 69 days, during which period there was an inch of rain. An inch of rain at Seathwaite is not very much, but it still shows that it was not an absolute drought, and there was no other drought of more than 40 days. With respect to the droughts in the upper parts of the district I have taken out the two dryest months during the whole period embraced by those tables so far as I can ascertain. I find that two droughts occurred, in March and April 1852 and in April and May 1861. There was only one station which had two months without any rain, and that return is unsupported by the returns from the nearest station, whereas it should be noticed that those droughts, and they are the only ones of any account in the district, occurred in two years remarkable for the greatest rains of all, that is to say, the years 1852 and 1861.

464. (*Mr. Harrison.*) You think that 77 inches is an average which may be relied upon ; what do you take to be the fall which might be relied upon in the driest year within your observation ?—In the driest year I should take it at something like 66 or 68 per cent. of the average fall, and the average being 77 inches, that would give about 53 inches.

465. That, of course, is the standard for the driest year ?—Yes, certainly ; but I believe as a rule engineers reckon upon the three driest years, that is to say, the mean of three successive dry years, and that gives 62 inches. I am not sure that it would ever fall as low as what I have stated ; it is just possible that it might, but certainly it is the very lowest. I may add that all through I have been guided simply by taking a perfectly safe quantity, that is to say, if a figure was 58·5, or anything under, I have always taken it at 58 inches, so as to be perfectly safe.

466. (*Chairman.*) You put not less than 77 inches for the mean rate over the whole district ?—Yes, not less than 77 inches.

467. Have you received the returns of the six gauges in the Welsh district which Mr. Bateman put in ?—Yes I have, but I should not like to express any definite opinion upon them, because we have not the same facilities for comparing them with previous years which exist in Cumberland. In the Cumberland district the gauges have been at work for very many years, and consequently a limited period, by the process which I

G. J. Symons, Esq.

14 Feb. 1867.

have described, can be reduced to represent the true average of a long period. In the absence of those long established gauges it is very difficult to do anything of the sort. I do not say that it is an impossibility, but it is a thing upon which I should rather hesitate before I entered. The only thing which is much of a guide is afforded by another table which I have put in. I do not know that it is much of a guide as to the value of them, but it shows at any rate the ratio of the year 1866 to the period of years there given. It is a very short table, simply containing the average fall at some stations. They are not in Mr. Bateman's district, with one exception, and of course they might be excepted to on that ground, but there are no long established gauges in his district, therefore we are obliged to go further afield. It will be seen from the table that the percentage of excess in 1866 was very nearly the same in Cumberland as in Wales. (*The witness delivered in the following table.*)

RAINFALL IN WALES.

Date.	Lampeter.	Rhayader.	Llanidloes.	Hawarden.
1855	32·37	—	—	21·80
1856	41·02	—	—	25·90
1857	40·00	—	—	28·10
1858	36·69	35.11	—	21·70
1859	45·82	50·72	—	30·50
1860	55·30	59·52	—	27·80
1861	43·98	40·73	—	21·82
1862	43·22	47·81	—	30·37
1863	45·38	42·72	—	23·06
1864	32·58	37·02		21·67
1865	42·39	41·48	43·33	21·96
1866	50·86	51·05	58·07	29·82
Mean	42·47	(9 years) 45·13	—	25·37

From this we find that the rainfall of 1866 exceeded the average at Lampeter by 20 per cent.
Rhayader by 13 per cent.
Hawarden by 18 per cent.
giving a mean excess of 17 per cent., closely approaching to the same excess as in the lake district.

G. J. SYMONS.

468. You have given in this table a place called Lampeter, in what part of Wales is that ?—That is in Cardiganshire.

469. And you have given a series of rainfalls for 11 years ?—Yes, 11 or 12 years.

470. And you make out there that the mean fall was 42·47 inches ?—Yes; whatever value is stated in the table I believe to be so.

471. The other place is Rhayader, for a period of nine years, and the mean fall you state to be 45·13 inches ?—Yes.

472. Then at Llanidloes you give only two years' gauging; in one year it was 43·33 inches, and in the other 58·07 inches ?—Yes, those were the values.

473. Would Hawarden, which is in Flintshire, bear any relation to Mr. Bateman's scheme ?—It is scarcely so, but at the same time it is the best thing that can be done. I should not say that you must take it as any guide as to the quantity by any means, but you may take it as a guide as to the ratio of the year, that is to say, if it was a wet year. In Mr. Bateman's district (*pointing out the same on the map*) there is no gauge within the district which will give us any guide as to whether 1866 was a wet year or a dry year, or how wet a year it was. Gauges have recently been established over this district, but only for about two years, therefore they can be no guide, consequently I am obliged to fall back upon Rhayader, which is a little below the Bangor district, and Lampeter, which is still further below, as a counterpoise, and Hawarden would be to the north-east, consequently a line drawn between the points which I now designate on the map would pass very nearly over Mr. Bateman's district, and as I said before it simply affords the best indication which can be obtained.

474. (*Mr. Prestwich.*) Those points are just upon the outskirts of Mr. Bateman's district, are they not ?—They are.

475. Would not the difference between the fall in the central area and the outskirts be relatively the same in the one district and the other ?—The difference would be the same, decidedly, but the absolute quantity of course is larger in the centre of the district.

476. (*Chairman.*) The fall in the central district is larger than when the district goes into the lower country ?—Yes. As far as Hawarden is concerned it is a dry spot, just as we have dry spots when we get a considerable distance on the further side of Penrith; it is astonishing how quickly the rainfall falls off. When you go 10 or 12 miles on the other side of Penrith you get a mean rainfall of 28 inches instead of 77 inches. So again, I believe the effect of the Snowdon range and the mountains round there is to draw down the water and leave it dry over Denbighshire, Flintshire, and that neighbourhood.

477. (*Mr. Prestwich.*) Therefore you must have gauges in the actual districts themselves to enable you to come to a conclusion ?—Yes.

478. Do you not consider that the conditions with reference to the fall of rain in those two areas, the Welsh district and the lake district, are similar ?—They are similar, except that the lake district always has very much the largest fall, very much larger than it is in Wales.

479. (*Chairman.*) If no gauges have been established in the Welsh district excepting a very short period, how can you come to a satisfactory conclusion that the rainfall in the lake district is a great deal more than the rainfall in the Welsh district ?—Because wherever we have had gauges in Wales they have been fragmentary, they have been in operation for one or two years, or perhaps for one year, or for two half years, so that they are not available to enable us to arrive at an accurate conclusion.

480. We are alluding at this moment more particularly to the district from which Mr. Bateman proposes to draw his supplies, where we understand that the gauges have only been in existence three months ?—Mr. Bateman's gauges have only been in existence three or four months.

481. In the absence of gauges in that district, except within the last three months, would it be safe to say that the rainfall in the lake district was a great deal larger than the rainfall in the Welsh district ?—It would not, as applied to Mr. Bateman's district, absolutely, but to adjoining stations; the fragments are not available for reducing to standards of returns, which is what I am referring to, because they are so very fragmentary, but so far as they go we have never, until this year, had a return of 100 inches from any part of Wales. I do not say that no such quantity can be found, but as far as analogy goes, and so far as the returns from the neighbourhood of Snowdon and other parts go, there is not any indication of it; we may not have found wet places when Mr. Bateman may have found them, but at the same time there is no evidence excepting that of a few months to show it.

482. (*Mr. Prestwich.*) Are not the meteorological conditions similar, as far as exposure to the breezes is concerned ?—No; I have had experience with regard to that for years, and therefore I may quote from a paper which appeared in some publication of the British Association, some years ago, of the relative rainfall of the two districts, when I first established about 25 gauges about Snowdon, and I there pointed out that it was a very singular thing that the Cumberland district lies exactly in the line which Mr. Henry Eaton, I think it was, had pointed out as the line along which greater part the English storms travelled, and that the centre of storms seemed to pass just over that line; and it was a question whether or not that might not amply account for the excess there. It is quite a theoretical matter, it is not a matter upon which anyone can speak positively, but at the same time it is a singular coincidence.

483. Supposing you were to classify the different

areas in England, so far as the extent of rainfall went, would you consider the lake district to be the district in which the rainfall was the largest?—Decidedly.

484. Have you a map in which you have shaded the rainfall over the different areas?—I have not, because until very recently I had not considered that it was safe to do so; such a map was published by Mr. Keith Johnstone many years ago, ten years probably, but that map was shaded on very indifferent observations in many cases, and I felt that if I were to put my name to a map I should wish it to be really trustworthy. Something of the kind I have just prepared for Mr. Stanford, and I believe it has been published, but that is not a shaded map, it shows the rainfall for the whole kingdom, and is a correct map on the whole, the amount being stated in plain figures.

485. (*Sir J. Thwaites.*) Will it be shortly published?—I have had copies sent up to me, and I believe it to be published. I think it is called Stanford's Hydrographical Map.

486. (*Mr. Harrison.*) How long a period should you consider to be absolutely necessary to have the observations extending over to enable you to form a correct judgment with regard to any particular district?—I think we require that the standard of returns should be not less than 10 or 12 years. In the absence of that it is very difficult to form any really sound opinion as to what temporary returns indicate, but by means, for instance, of the paper which I have handed in, that Welsh table, an approximation may be obtained.

487. Do not you think that by the result of three years' observation, and then a comparison during the same period with the rainfall of other districts, you could obtain a pretty accurate idea of what the average ought to be, taking of course such gauges as have been in existence, some of them at a little distance, for several years?—Yes.

488. You could by analogy obtain, could you not, a pretty close approximation to what the rainfall would be?—Yes, I should think within 5 or 10 per cent.

489. To what extent do you think that a whole year's observation would enable you in the same way to approximate?—That is rather a difficult question to answer. I found even at three of those Cumberland stations that the ratio of the year 1854 to the mean of 22 years, was 83 at one place and 103 at another, differing by 20 per cent. In fact they are the three best kept gauges we have in the kingdom, and therefore we must take it that the natural conditions vary certainly to the extent of 20 per cent. or one-fifth of the whole. You might possibly reduce it to closer limits, but I cannot say. I have never gone to work upon one year's observation without having standards all round it, close to it, and without them I do not feel safe as to what value could be placed upon them.

490. You have not had the whole of the particulars of the statement which was made by Mr. Bateman have you?—I did not hear his statement, and I have received simply the total quantity at each of the gauges in the three months, but when I came to examine the materials which really exist I found that they were such that I did not exactly see my way clearly to deducing the mean fall from them.

491. You do not think that by comparing districts of the country nearly similar in their main features, and by comparing the rainfall at the same periods in those different districts, you could from that form any approximate estimate or any reliable estimate?—Nothing like so reliable as the other way, and not an approach to it. If you take the mean of Mr. Bateman's returns, I think it was something like 18 or 19 inches. I have not the figures at hand, therefore I cannot speak positively.

492. (*Sir J. Thwaites.*) Do you know the district which Mr. Bateman proposes to take?—No, I cannot say that I know it from personal experience. I have been in the neighbourhood, but I have not gone over it in the same way as I have gone over the lake district. I know it principally from a careful study of the ordinance geological map.

493. You have stated that the lake district would give an average of something like 77 inches. Having regard to the pecular condition of the Welsh district from which Mr. Bateman proposes to take his supply, do you think that 57 inches would be near the mark as to the amount of rainfall?—The value at which I have arrived for Mr. Bateman's district is considerably lower than that.

494. But you take your gaugings at a lower point? You do not include the centre district, from which he anticipates the larger fall?—No; but the figures which I was just using I was using as gaugings for those three months, which, as I said just now, I think were 19 inches.

495. So that it would be four times that?—Yes; but I thought a simpler way would be to compare the corresponding three months in the lake district, and during the period in which Mr. Bateman had 19 inches the lake district had 30½ inches. Then if we take it as 31 : 19 : : 77 inches that gives 47. I do not say that that is a reliable way, but it is the best way that occurs to me.

496. (*Chairman.*) Might it not be quite possible that what was a very wet season in the lake district, might be a dry season in the Welsh district?—Yes, certainly, and for that reason I have prepared the table which I have just handed in, which shows that the year 1866 taken as a whole was very nearly as much in excess in the Welsh district, as it was in the Cumberland district; it was 17 per cent. in excess in the Welsh district, and 24 per cent. in excess in the lake district, which indicates a close analogy in two years.

497. (*Sir J. Thwaites.*) Mr. Bateman's reasoning was this, that having taken careful gaugings for three months they would give him an average of 76 inches, and he therefore concludes that there would be the same amount of rainfall in Wales, having regard to the conditions of the district as that which falls in the lake district; you do not concur in that view?—No, I do not. I do not see that the values which he has given, so far as I have been able to discuss them at present, support that view; they may do so, but I confess that I do not see it at present.

498. Your gaugings surrounding that district do not support it?—No, not at all; the old established gaugings in the district giving us something like 50 inches for the mean fall of the district.

499. If I understand you rightly the point at which your gauges were fixed were rather dry points in the Welsh district?—The old gauges I believe were at dry points, and therefore I think that the 50 inches which all the old observations give as the outside fall for Wales should probably be raised to 55, or something of that sort for the true fall, taking in the hilly district as well.

500. Taking the hilly district, and eliminating the district which you have gauged, would the hilly district yield a larger amount of rainfall than 55 inches?—It might do so, but whether it would or not I certainly am not competent to say.

501. Judging from the analogy of the higher lands in the lake district presenting a westerly aspect, and catching the westerly winds, would you not have similar results on the Welsh mountains to those which you have in the lake district?—Yes; but the low stations in the Welsh district do not give such a high value as the low stations in the Cumberland district, take for instance Seathwaite, that is admittedly exceptional, but still we have 140 inches per annum there at 400 feet above the sea.

502. How is that situated, is it in a gorge or not?—The Seathwaite gauge is scarcely in a gorge except that all that part of Cumberland is more or less of the nature of a gorge, but still it is a moderately wide valley, perhaps half or three quarters of a mile across.

503. Would not the moisture be carried rapidly through and deposited at a lower point?—The rain comes from the south-west along the valley, and is deposited in this part (*pointing to the map*), and is unable to get over the ridge.

504. What is the result of that gauging?—140

G. J. Symons, Esq.

14 Feb. 1867.

inches, and a little further up the valley it is 180 inches at a place called the Stye.

505. Then judging from analogy that whereas a larger quantity of rain falls in the lower district, in what you might call the dry district of the lake district, than falls in what you might designate the dry district in the Welsh area, you conclude that on the whole there is a larger fall of rain within the plain in the lake district than in the Welsh district?—Decidedly.

506. That is the process of your reasoning, and that is the result?—Yes.

507. (*Mr. Prestwich.*) I see that at Keswick the mean annual fall is given as 60 inches?—Mine comes out 58·53, as against 60.

508. What distance is Seathwaite from Keswick? Nine miles, and the rainfall at Seathwaite is about 140 inches.

509. That shows the heavy rainfall to be centred in small areas?—Just so, so far as that part is concerned; it is astonishing, as I before explained, how very rapidly the heavy falls decrease in certain directions. In other directions from Seathwaite you may go from 20 to 30 miles and keep up to the average 100 inches all the way, whereas if you go upwards from Seathwaite to Keswick you drop down to about 60 inches.

510. Is any part of the rainfall of Seathwaite due for depositing in Thirlmere lake?—I believe not; it runs into Derwentwater. The Easedale Tarn is a very wet district, which at present goes into Grasmere, I believe; but by the proposed plan it is to be conducted into Thirlmere.

511. (*Mr. Harrison.*) Can you illustrate that clearly by a reference to the figures on the map?—Yes.

512. Will you do so?—Yes, I should be very happy to do so. (*The witness described the same on the map.*)

513. (*Sir J. Thwaites.*) At the head of Haweswater you get 52 inches, do you not, and at the lower part 108 inches?—Yes.

514. Would it not be a very satisfactory experiment in the promotion of your scientific pursuits to test the actual discharge from Haweswater, calculating the amount due to the gathering area, and what would go off as the net result?—I should be delighted to do so.

515. You would deduct the absorption and evaporation, and you would then have something reliable?—Yes.

516. But of course that would depend, would it not, a good deal upon the nature of the soil?—Yes; taking the amount of rainfall into the lake and the amount running off.

517. Have you ever done that in the course of your studies in meteorology?—Unfortunately I have not the means of doing that, or else I should be very glad to see it done.

518. I presume that the principal difficulty is the expense of fitting the mode of discharge for the purpose of gauging?—The expense is the principal difficulty.

519. Do you remember if any given area, depositing its water into any lake or reservoir, has been so gauged. I mean the water that has been ultimately discharged from it?—Yes, I believe so, in several instances.

520. Can you name any?—I think that they draw from Glencorse the water supplied to Edinburgh in that way. I do not think that I can name any instances from memory, although I have repeatedly seen a list of ten or a dozen places in which such calculations have been made.

521. In cases where the area of fall has been sufficiently defined?—Yes, and where the rainfall has been gauged by one or more instruments in different parts, and the amount running off has been registered each day, and the total taken for a period.

522. Has it been free from any draught within the geological basin by means of deep wells?—That I am unable to say.

523. Because, in order to ascertain the fact, the basin must be full?—Of course it must; and I am inclined to think that all the experiments that have been made in that way have been in districts where there has been infinitely more percolation than there could be in the lake district.

524. (*Colonel Harness.*) Do you know whether any observations have been made upon the rainfall in the west of Ireland with regard to the rise and fall of the lakes?—I am aware that there have been such observations, but I have not had time to see them.

525. (*Sir J. Thwaites.*) Then the calculation that 12 inches is the mean of what is abstracted by means of absorption and evaporation is after all a theory?—To a great extent it is a theory based upon the facts which have been observed in other districts.

526. (*Mr. Harrison.*) Have you looked through the evidence given by Mr. Bateman on the 6th of February, page 5, and on the 7th of February, in the first and following pages?—Yes, I have.

527. Have you examined particularly the conclusion at which he arrives from the different statements which he has made?—Yes, I have; I find that he draws two principal conclusions. In the first instance he assumes throughout that the year 1865 was an excessively dry year, one of the driest years on record (in fact he frequently speaks of it as the driest on record), whereas really, as far as I am able to ascertain, it was about 13 per cent. below the average; and in the year 1853 it was 17 per cent. below; in 1856 it was 25 per cent. below; in 1857 it was 21 per cent. below; and in 1858 it was 19 per cent. below. The average of the last four of those years, that is to say, the four years from 1855 to 1858, was a deficiency of 26 per cent.—twice as great a deficiency as existed in 1865, simply showing that 1865 was not absolutely to be looked upon as an excessively dry year.

528. Does not Mr. Bateman refer to it as a dry year as specially applicable to Wales?—He refers to it as such on page 5; but you will observe that in answer to question 24 on page 6, he says: "The general "average of the whole of the remainder of the lake "district may be taken in an averege year at pro- "bably 70 or 80 inches, and in a year of drought, "like 1865, at 60 inches." He has just been speaking of the whole of the districts of Scotland, Wales, and Cumberland as being so strictly analogous. Then Sir Benjamin Phillips goes on to ask him, "What is that as compared with the Welsh district?" to which he replies: "The same. I do not believe that there is any "difference between the rain falling in North Wales "and the rain falling in the lakes;" making it therefore apply to the Welsh district. Then again, at the top of page 8, after saying that "We should be justified "in taking the average at something like 75 inches "of rain for the district in Wales," he goes on to say, "That was about the amount of rain in 1865, which "was the very driest year." So that he appears to consider that it does apply to Wales. One of these tables which I have produced illustrates it. The fall in the year 1865, at Rhayader, was 41½ inches; in 1864 there was a fall of 4 inches less, only 37 inches; there was the same fall as near as possible in 1863; and in 1858 there was only 35 inches, 6 inches less than there was in 1865. I do not know that it is a very material point, but it still shows that 1865 cannot be regarded as anything like the minimum for which provision should be made.

529. Looking at all those figures, which are presented in Mr. Bateman's evidence, do you think that he has calculated it too high when he takes 36 inches as that which he may safely take as the available rainfall?—If I understand 36 inches as the amount to be relied upon as the available quantity of water to be taken away from the district in a year of drought, that is to say the 36 inches which he speaks of, for he says, "I only take 36 inches out of the 48 inches," I should suppose that that means that he would have 36 inches available out of the 48 inches falling on the district in the driest year.

530. (*Mr. Prestwich.*) I do not think that that is quite the way in which he expresses himself?—It

occurs on page 1 of the second day's evidence, February the 7th.

531. I think he considered that there were 48 inches available out of the fall, but he would not take the extreme quantity which he considered available, but only 36 inches?—If there were 48 inches available it would require an addition, roughly speaking, of 10 inches for loss by evaporation and other causes, which would raise it to 58 inches.

532. (*Sir J. Thwaites.*) I think he took 12 or 13 inches for loss?—Then that would make it still more, only I did not wish to make it extreme.

533. (*Mr. Harrison.*) I think that he takes 12 inches from the 48, leaving 36 as the available rainfall for all his purposes?—That was the impression upon my mind, but at the same time I did not feel safe about it.

534. (*Mr. Prestwich.*) At page 6 of the first day, near the bottom of the page, he says, "But the general "average of the whole of the remainder of the lake "district may be taken in an average year at probably "70 or 80 inches, and in a year of drought, like 1865, "at 60 inches." There he allowed 12 inches for loss, leaving 48 inches for collection?—Yes.

535. But out of that 48 inches he only took 36 inches, allowing for the loss?—I think he is quite safe in stating 36, but I do not see how he can reckon upon the other, and partly for this reason, the mean of his returns is 19 inches for the three months of October, November, and December last year, and the mean of the corresponding period in Cumberland was $30\frac{1}{2}$, or say 31 inches. This would apparently indicate that the fall in the Welsh district was two-thirds of that in the lake district, namely 20 inches in Wales against 30 inches in Cumberland. If so, and if we apply that to the means deduced from the short period gauges in the lake district, they gave a mean of 82 inches, and two-thirds of that would be 54 inches; but I have shown that the real mean in the lake district may be taken at 77 inches, and this would give a mean for Mr. Bateman's district of 51 inches; and the mean of course for the three dry years would only come out 41 inches. I should say, from general knowledge, irrespective of the value so given, that that is below what really exists in that district.

536. You would rather draw a comparison between the one and the other from three months?—Yes, the difficulty in answering, which no doubt the Commission noticed that I felt, with respect to the Welsh district is this, that we have nothing, or scarcely anything with which to compare what we have got. At the same time what we have by no means supports what Mr. Bateman says, that there is the same fall in Wales as there is in Cumberland. I am inclined to think that it may be taken, roughly speaking, at two-thirds of the Cumberland fall.

537. Can you state what the rainfall was at Keswick in 1865?—49·18.

538. I see that Mr. Bateman gives the fall at Dolgelly, which is at the foot of the mountains in the same way as Keswick, as 57·59?—Yes, if we take the case of Dolgelly there are two guages there, one of them, which appears to be at the very low elevation of 43 feet, gives 52 inches, and the other at 500 feet gives 57 inches, making a difference of five inches between the two gauges. Perhaps I may be allowed to put in this pamphlet, which contains the rainfall in the year 1865 (*handing in the same*).

539. (*Mr. Harrison.*) I think you make out that the least rainfall in the Cumberland district, specially referred to, would be 53 inches?—That would be in one year of excessive drought.

540. But taking the average of three years you make it 62 inches?—Yes, 61 or 62.

541. Then are we to understand that comparing that with the Welsh district, you would not consider it safe to take more than two-thirds of that amount, or say 41 inches?—I consider that the observations, so far as they have gone, indicate that. At the same time, my own experience, and my own general impression would be, that rather more than that must be expected, but I do not see any weak point in the calculations which I have made; I do not know where it is if there be one. The old established gauges in the Welsh district all give a lower mean value than those in the lake district; in fact I may just point them out on this large map. We have a gauge at Bala, at the head of the lake, and we have one at Rhayader, and we have others further south, and they all give somewhere about 49 inches for the mean annual fall. If you take two-thirds of that 49 inches you get something like 33 inches for the fall in the one very dry year. But Mr. Bateman's values show that the fall in the mountains is far in excess of that which we have at those low places, and therefore that 33 inches might be raised probably to something like between 40 and 50 inches, for the higher parts are the wet parts of the district. It is just the same thing with respect to the existing Welsh stations as it is with respect to the Cumberland ones. The old Cumberland stations, with the exception of those started by Dr. Miller, gave rather low falls. When the Welsh district was regularly examined, much heavier falls were found in certain places, but in Cumberland they are found all over the district, as I have shown, right across to Shap, whereas in Wales, as far as they have been found, they are apparently more detached with dry places between them.

542. From a rather more extended consideration of those facts which Mr. Bateman has stated, taking the rainfall that you have, extending over the same period at Rhayader, Bala, and Llanidloes, and then taking into account the three months' returns which he has made, and comparing those three months' returns with the fall for the same three months at the other stations, of which you have observations extending over a long period, do you think that you could arrive at any more approximate and reliable opinion as to what would be the probable rainfall in the Welsh district?—I think that that mode of proceeding is probably the safest, and it would very likely be more correct than what I have been able to do now. To do that of course I should have to refer to the monthly returns for the past year, which I have not now with me, but I should be very happy to do so if the Commission desire it.

543. How many years have those other gauges been kept at Rhayader, Llanidloes, and Bala, and two or three other places?—That at Rhayader has been kept nine years, and that at Llanidloes has been kept two years. There are returns from Bala of a more or less fragmentary nature for about two and a half years. There is nothing else near, and indeed nothing else, as far as my memory goes at present, that will serve as a standard for comparison.

544. Then the observations for the three months are in the actual district intermediate and nearly in a line between Hawarden and Lampeter?—Yes.

545. Taking the comparative heights at which those observations have been made, and with your knowledge of the lake district of Cumberland, and the relative heights of the positions in which the gauges are kept there, do you not think that if you were to give all your mind to the study of those facts which we have, you might be able to arrive at something like a pretty approximate opinion, of course without tying yourself to it, but a pretty fair opinion as to what the probable rainfall would be?—I should be very happy to do the best I can to work it out in that way. I think that I might probably get an accurate result within 10 per cent., or something of that sort.

G. J. Symons Esq.

14 Feb. 1867.

The witness withdrew.

R. Hassard, Esq.

14 Feb. 1867.

RICHARD HASSARD, Esq., examined.

546. (*Chairman.*) You are a civil engineer, I believe?—Yes.

547. And a member of the Institute of Civil Engineers of England?—Yes.

548. You are well acquainted with hydraulic science, and have had, have you not, a great deal of experience in designing works for the water supply of towns?—Yes.

549. Will you give us the names of a few of the towns which you have supplied with water?—I constructed gravitation works for supplying the city of Londonderry, in Ireland, with pure soft water, at high pressure, on the constant system. When I was in the employment of another gentleman some years ago, Mr. Ranger, I designed works for the water supply of Southampton, Dartford, and Worthing, which were pumping schemes. I also designed for the same gentleman a large gravitation scheme in Yorkshire, which was thought a good deal of at the time, and was for supplying from the head of the river Don, at Dunford Bridge, the towns of Dewsbury, Batley, and Heckmondwicke. My professional connection with Mr. Ranger ceased after the Act was obtained, and I had nothing further to do with the works. I mention that because I believe there were some errors of construction in carrying those works out, but for them I was not in any way responsible. About six years ago I was the successful competitor in the case of the Dublin waterworks. Several engineers of repute put forward projects for the supply of that city, and amongst others there were projects put forward by Mr. Bateman and by Mr. Hawksley, both well known as waterworks engineers, but the project which I had designed and advocated, although it involved bringing water from a much greater distance than any of the other projects, and necessitated apparently a greater outlay in the first instance, received the recommendation of Mr. Hawkshaw, the Royal Commissioner, and the works are now almost completed.

550. What is the distance from which you brought the water to Dublin?—It was about 26 miles from Dublin, at a place called Roundwood, on the river Vartry. The drainage all flowed southward, and my plan was to reverse it and take it northwards to Dublin, somewhat in the same way but in a contrary direction to what is proposed in this project. The project also in another respect was somewhat similar to this one, inasmuch as it was laid out for the supply not only of Dublin, but of several places along the line of the aqueduct. I am also engineer to the Sligo Corporation waterworks, for which the sanction of Parliament is now sought to be obtained.

551. What quantity of water per head per diem do the Dublin people require?—The supply is estimated for 40 gallons per head per diem; the population is 300,000, and the estimated quantity is 12,000,000 gallons.

552. Could they get more in Dublin if they wished it?—That supply can be extended to a much larger amount, if necessary; a greater area of drainage ground can be taken in.

553. Do you find practically that in Dublin 40 gallons per head is the limit of what they require?—That is what those works were laid out for in the first instance, with the facility of extending them afterwards if the necessity arose.

554. (*Mr. Harrison.*) They are not completed yet, are they?—The works are nearly completed, but the water is not yet introduced into Dublin.

555. (*Chairman.*) The distance that you bring the water you say is 26 miles?—I think that is the distance, speaking from memory.

556. What area does the gathering ground cover?—The gathering ground covers 19 square miles, or something about 13,000 square acres.

557. Your experience appears to be very great in water engineering, and you say that your works were constructed in Dublin to supply 40 gallons per head, what quantity per head per diem should you consider necessary?—I did not construct the works; I designed the scheme. The Corporation paid me a premium for the design, and then they carried them out by their own officers, in every respect almost identical with the way in which I had projected them.

558. Is 40 gallons per head the extent of the supply to Dublin?—40 gallons is the first instalment, and it can be increased hereafter if necessary.

559. In your opinion is 40 gallons per head per diem sufficient for a large population such as that either of Dublin or London?—For Dublin probably it might be sufficient, for Dublin is a city in which there is very little trade or manufacture, speaking comparatively, and water, especially soft water, when it is introduced into any town is very largely used for all purposes of manufacture. It is found to be the case in Glasgow, Manchester, and Liverpool, and in every town in which it has been introduced. In fact in Glasgow the amount derived from the sales of water for trading and manufacturing purposes I think is nearly double, or something of that kind, the amount derived from the rates. I shall put in tables which will explain that quite clearly.

560. We have it that at Glasgow the amount supplied is 46 gallons per head per diem by Mr. Bateman's scheme?—I believe that it is generally taken at 50 gallons, there is no doubt great waste.

561. What would you consider to be a proper and sufficient quantity of water per head per diem for London?—I do not think that any project which would not eventually supply, or was not capable of supplying 50 gallons of water for each individual of the population should be entertained, and it should not only be capable of supplying 50 gallons per head to the present population, but it should also be capable of supplying 50 gallons per head of the increased population that we may reasonably expect in 20 years after the completion of the new works, the supply being increased from time to time as the demand for the water arose.

562. (*Sir B. Phillips.*) You take for the present 50 gallons per head per diem, with facilities for increasing *pro rata* with the population?—Precisely.

563. (*Sir J. Thwaites.*) You stated, did you not, that your gathering ground in Dublin was 13,000 acres?—Speaking from memory, I think that that is so.

564. What is the rainfall that is due to that area?—I can only speak from memory. I think that the net available rainfall was in that case taken at 15 inches.

565. (*Chairman.*) Can you state to the Commissioners the whole rainfall, what you take for corporation purposes, and then what is left for absorption and compensation?—I shall put in a statement of that. I am only speaking from memory, and I do not recollect the figures exactly.

566. (*Sir J. Thwaites.*) Is it a mountainous district from which you derive your supply to Dublin?—It is a hilly district; the geological formation is partly granite and partly silurian, the same as the lake district. It is a hilly district, the mean elevation being about 1,060 feet above the sea.

567. In designing your scheme for the city of Dublin, you must have carefully gone into the question of rainfall, and how much would be the net result due from that 13,000 acres?—I did so very carefully; I estimated it there at 14 inches.

568. Are you able at this moment to state to the Commissioners the actual rainfall?—I shall put it in.

569. Would it be 40 or 50 inches?—No, the rainfall was not so high as that; it is on the extreme eastern coast of Ireland, with a great area of country for the rain clouds to pass over before they reach it, and there is a great deal of elevated ground on the western coast, which intercepts more or less rain; it was between 30 and 40 inches.

570. Assuming that it was 35 inches of rainfall, you lost, did you not, 20 inches?—No; I estimated the loss

at 14 inches in that particular instance leaving 21 inches as available for supply and compensation.

571. Did not you state that the available quantity was 14 inches?—The available quantity that was taken for the mean of three dry years was 14 inches, that is for town's supply, exclusive of compensation. That was the quantity upon which the calculations were based, as far as my memory serves me.

572. Supposing the actual fall during those three years was 35 inches, and it could scarcely be less, I apprehend you lost 21 inches, if you had a remainder of 14?—No. I say that the scheme was laid out to be capable of supplying Dublin, after giving compensation in water, with a remaining depth of only 14 inches, because at the time that those works were designed there were no rain gauges in the country, or in the district which would enable us to form any reliable estimate, and therefore in order to insure the perfect working of the scheme a drainage area was secured on which 14 inches of available rainfall would supply 12,000,000 gallons daily to the inhabitants of Dublin.

573. You are not aware at this moment as to the margin beyond 14 inches?—I am not, but I can ascertain it.

574. You fixed upon 14 inches as the quantity which you thought would be derived from that area?—Yes; I fixed upon an area, which with 14 inches of available rain, would give a daily supply of 12,000,000 gallons.

575. I understand that those works are not finished, and are therefore not in operation?—They are not quite finished.

576. You do not know to this date, do you, what will be the result of those 13,000 acres?—Yes; gauges have been kept for the last six years in that locality, and I know that a much larger quantity of rain than we had reckoned upon as available (that is 14 inches) has turned out to be available for the works.

577. You mean that plus the evaporation and absorption?—Yes, much larger than the estimate.

578. What is the length of your aqueduct?—The total length of aqueduct is 26 miles.

579. Is it open cutting all the way?—No, it is not open cutting any portion of it, except a very small bit just below the reservoir, before it enters the tunnel; there is a tunnel through the ridge.

580. What is the size of the tunnel?—I did not construct it; I think it is about 5 feet square.

581. Do you know the fall?—I think it has a fall of two feet per mile, but I am not positive. I did not carry out the works; I only designed the scheme. I did not design the actual works, or make the working drawings.

582. (*Mr. Harrison.*) You were engineer, were you not, for the scheme, who deposited the plans and carried the bill through parliament for the construction of the works?—No, not so; I was the engineer who furnished certain plans to the corporation on which they prepared the parliamentary plans, and went to parliament through their own officers, to secure a scheme identical with the one I designed.

583. (*Sir John Thwaites.*) Then your plan was selected, I presume, as the result of competition, as the best plan of supplying pure water to Dublin?—Yes.

584. So far as the sections and detailed matters of that kind are concerned you are not able to give evidence?—Just so; it was the general project that I designed.

585. (*Chairman.*) How long since was it that the project for supplying the metropolis and towns in the manufacturing and midland districts and deriving its supply from the natural lakes of the north first suggested itself to you?—About three years ago.

586. What steps did you take for satisfying yourself of the feasibility of the plan?—My first step, of course, was to get the ordnance maps showing all the levels of the district. Having got the maps of that district all contoured, you have all the levels and heights of the country upon them, and the eye of anyone accustomed to study them takes in at once the whole features of the country. Having got those maps, I satisfied myself of the feasibility of the project, and I communicated the idea to Mr. Hemans.

587. You must have done more, I apprehend, than getting the levels?—Yes, that was the first step that I took.

588. In order to satisfy yourself of the feasibility of the plan you must have gone into the question of the rainfall?—Yes, and I visited the locality as well. The first step was to procure maps showing the elevations of the locality; the rainfall was notorious; and I then visited the locality and projected the scheme.

589. You communicated it to Mr. Hemans, and since that you have worked the plan out together?—Yes; Bala Lake has since been incorporated in the project in order to replace water which might be advantageously sold to the manufacturing towns of the north.

590. (*Sir J. Thwaites.*) That is to say your tunnel would be nearer to some large towns, and you would supply those towns more readily than by taking the water direct from Bala?—For instance at Liverpool, which is very much in want of water, and the towns adjacent, if a quantity of water—we will say for the sake of example 50,000,000 gallons a day—were sold to that district, I should replace that quantity with 50,000,000 gallons of water taken from Bala, and having made up the deficiency I should carry on the 250,000,000 gallons to London; in fact, instead of supplying Liverpool from Bala, I should supply Liverpool and the adjacent district from our aqueduct, and carry the Bala water on to London.

591. You would compensate for the abstraction by taking that quantity from Bala?—Yes.

592. (*Sir B. Phillips.*) What is the distance from your aqueduct to Bala?—It is about 65 miles, I think. It may be 70 miles probably.

593. According to the map on the wall the nearest large towns to Bala would be the potteries?—The potteries would be very near the point where the Bala water would come; those towns are very nearly at the point at which the water from Bala would be brought in. The water from Bala would be at an elevation of probably 70 or 80 feet higher than the water in the main aqueduct, and it would be a very proper course of proceeding then to take the residue of the Bala water on, if necessary, for the supply of Wolverhampton, Birmingham, and that locality.

594. If by your scheme you propose to supply water from Bala would you run first to the towns in the potteries, and then to Congleton, Leek, Macclesfield, Stockport, Manchester, and so forth?—The water would flow in the other direction running southward.

595. (*Chairman.*) You would bring the water from the Lake district and supply the towns on the route between the Lake district and Stoke, and the water which you so abstract from your system between the Lake district and Stoke you would replace from the Bala district?—Yes, we should make it up from Bala.

596. (*Sir J. Thwaites.*) That would be 80 feet higher than the other aqueduct?—Yes, than the main aqueduct.

597. And, as I understand you, that scheme would be 70 miles in length?—Yes, about 70 miles in length.

598. And that would give you very little over a foot of fall?—About a foot of fall per mile.

599. Do you think that sufficient?—Yes, quite so.

600. (*Chairman.*) What advantage do you anticipate from this method of dealing with the district, namely, having an additional supply as it were from Bala?—There would be one point of great advantage, for instance: if I were constructing that scheme, I should make a reservoir at the point of junction of the Bala conduit at Stoke capable of holding about 21 days' supply; the regulating reservoir near London would hold 15 days' supply, making 36 days, and the yield from the Bala district for that period would be equal to about 7 days in addition, making a total storage or reserve equivalent to 43 days' supply.

601. You use the word "if." Is not the supplying of water from Bala in the manner you have described

R. Hassard, Esq.

14 Feb. 1867.

a part of your scheme?—It is an adjunct of the scheme.

602. Then it is not part of the scheme?—It is part of the scheme for supplying London, and the manufacturing towns in the provinces, from the Lakes in England and Wales.

603. (*Sir J. Thwaites.*) Will you first give us a description of your scheme proper, and then deal with this exceptional supply?—The main project is for bringing water to London from the Lakes of Cumberland and Westmoreland.

604. (*Chairman.*) May we take this to be your project, that if you merely brought the water from the Lake district to London you would not make use of the water from the Bala district, but that if you parted with any water between the Lake district and London to any of the places on the road, such as Liverpool, Manchester, Stockport, or Macclesfield, you would then consider it necessary to carry out the Bala project?—That is what I intended to convey.

605. (*Sir J. Thwaites.*) You state that after procuring the plans and examining generally the character of the district, you walked it?—Yes.

606. And finding the rainfall notorious, you designed your scheme?—Yes.

607. Finding the average of the rainfall to be 77 inches, what do you anticipate will be at your disposal when it finds its way to your reservoirs?—I take the returns at other places for the three driest years in succession. The three years 1853, 1854, and 1855 were consecutive years of very great drought; the quantity of water which fell in those years at the Rivington reservoirs, for supplying Liverpool, was 87 per cent. of the mean rainfall of 17 years. On the drainage ground of Loch Katrine, during the three years 1855, 1856, and 1857, which were also dry years, although not quite so dry as the previous years, the rain which fell on the district was 83 per cent. of the true mean rainfall of 11 years' observations. They were not the same three years, because the observations for those same three years were not obtainable, but I have given 1855, 1856, and 1857, which were also very dry years, and I say that during that period the rain which fell at Loch Katrine was 83 per cent. of the true mean rainfall of 11 years.

608. Do you mean that 83 per cent. was reservoired?—No, but that the mean rainfall of three consecutive dry years was at Liverpool 87 and at Loch Katrine 83 per cent. of the true mean annual rain.

609. Then there was a loss of 13 per cent.?—The amount of rain which fell was less than the mean average rain by 13 per cent. in the one case, and by 17 per cent. in the other.

610. Taking a dry year, I presume the abstraction by absorption would be greater in a dry year than in a wet year?—The loss is always greater in dry years.

611. Therefore this average would be, in your judgment, fair?—Yes, I take it at 83 per cent. as the lowest.

612. Did you apply that average to the district from which you propose to take your supply?—Yes, and that gives the result of 63·91 inches, or say 64 inches, of rain as the mean of three consecutive dry years.

613. (*Chairman.*) When you speak of dry years you have given us three dry years, 1853, 1854, and 1855, at Liverpool, and you have given us 1855, 1856, and 1857 at Glasgow?—Yes, which were also very dry years, but the returns at Loch Katrine for the years 1853, 1854, and 1855 were not published, and I am not aware what they were.

614. Even supposing they had been published, it would be quite possible, would it not, for 1853, 1854, and 1855 to have been exceedingly dry years at Liverpool, and by no means dry years at Glasgow?—They were notoriously dry years on the whole west coast of Britain.

615. (*Colonel Harness.*) Do you mean that the rainfall in those years was 83 per cent. of the mean of the average of the years which you have mentioned, or do you mean that 83 per cent. of that average was stored?—No; in the first case, at Rivington, the rainfall for those three consecutive dry years was 87 per cent. of the mean average rain.

616. (*Sir J. Thwaites.*) My question was whether the 87 per cent. was 87 per cent. of the rainfall due from the gathering area for the Liverpool supply in 1853, 1854, and 1855; that is to say, whether they actually caught 87 per cent. of the whole of the rainfall which was stored and found its way into the reservoir?—No.

617. Will you just explain what you do mean?—The mean rainfall at Liverpool for 17 years ending 1865 was 45·70 inches. The rainfall of the three dry years 1853, 1854, and 1855 was as follows: In 1853 the rainfall was 37·25 inches; in 1854 it was 43·36 inches; and in 1855 it was 39·12 inches; and the mean of those three dry years was 39·91 inches, which, as I have stated before, is 87 per cent. of the mean of 17 years.

618. My point is this: I want to know whether, from your observation of the rainfall of the area supplying Liverpool, you can state what percentage of that rainfall finds its way into the reservoirs?—I cannot tell you for any former year, but I can give it you for the years 1861, 1862, 1863, 1864, and 1865 at Liverpool. In the year 1861 the rainfall, as measured by the gauges, was 46·38 inches; the loss was the difference between this and 35·77 inches, being 10·61; that is to say, the loss out of 46·38 inches was 10·61 inches. In the year 1862 the loss out of 48·51 inches of rainfall was 8·43 inches. In the year 1863, out of 51·01 inches of rain, there were 10·29 inches lost. In the year 1864, out of 39·03 inches of rain, there were 11·18 inches lost; and in the year 1865, out of 34·80 inches of rain, there were 11·45 inches lost. That gives us for those five years a mean annual loss of 10·39 inches.

619. Is that the result of gauging the water as it passed into the reservoir?—I presume so. I am quoting from a pamphlet published by Mr. Duncan, the engineer of the Liverpool waterworks, on the future water supply of that town.

620. (*Chairman.*) Are we to understand that those calculations which you have now given in are what you have taken from a pamphlet published by Mr. Duncan on the water supply of Liverpool?—Yes. The mean loss, as I stated before, appears to have been 10·39 inches.

621. (*Sir J. Thwaites.*) Can you tell us whether the gauging was made at the entrance into the reservoir or at the place where the water is discharged?—I cannot tell whether it is above or below.

622. Because between those two points there would be the evaporation, would there not, which is due to the surface of the reservoir itself?—Yes.

623. And which is considerable?—Yes, amounting probably to 27 or 28 inches; but then it must be remembered that the reservoir itself forms a very small area as compared with the area of the drainage. At Manchester, I think, Mr. Bateman gave it in evidence that the average loss was 13 inches.

624. (*Chairman.*) You have stated that this scheme suggested itself to your mind some three years ago, that you have walked over the district, that you have compared the levels throughout, and that you have taken the rainfall of that district, that you have made calculations as to what amount of water that would give you, and that you propose to take it in the first place to London, and if necessary, to replace from Lake Bala the water which you might furnish to the towns on the road which might require it. Will you have the goodness, beginning at the top of the map, to describe shortly how you propose to bring the water to London, and the various points of detail which Mr. Hemans left you to give us?—We propose, as Mr. Hemans stated yesterday, collecting additional water in Haweswater by conduits constructed along the hill sides, intercepting the streams in a westerly direction from the River Lowther, at a point called Cooper's Green, taking in Swindale Beck, and Naddle Beck, and in a northerly direction from a stream called Heltondale Beck, taking in Gill Beck, and Hows Beck on the way, and then we convert Haweswater into a large storage

reservoir. The only part of the locality where there is any peat is in the Swindale district draining into the river Lowther, and we therefore propose to apply the water of Haweswater as the least excellent of the whole, for the purposes of compensation.

625. The gathering ground of the supply of Haweswater appears, does it not, from the figures upon that map to be some 38 square miles?—Yes, the available natural drainage area is probably not more than half that, but that would be the available area when those catchwater drains are made.

626. How much of that district is peat?—A very small portion.

627. Can you give us the acreage?—I should think $\frac{1}{20}$th part; $\frac{1}{20}$th part would probably be, in round numbers, two square miles, and that would be 1,280 acres, and the peat is only in small patches here and there.

628. (*Sir J. Thwaites.*) Are you sure that there is no peat on the west side of the river?—There is a little peat here (*pointing to the map*), which occasionally colours the river Lowther.

629. There is peat, is there not, on the other side of Bampton Common. There is a very small quantity of peat; there is heath, as there is on all the Surrey hills, and the Bagshot Sands are covered with heath; but there are no mosses that colour the water to any extent.

630. You propose, do you not, to increase the depth of Haweswater 42 feet?—Yes.

631. And you propose to run a dam across at the lower end?—Yes, across the outlet of the lake, which is a very favourable spot for constructing it.

632. On that side where the figure 38 is have you not a very high mountain?—Yes.

633. And on the other side you have a series of small farms?—Yes, immediately adjacent to the lake itself, but it is a very narrow strip indeed; there are high mountains coming in on that side.

634. Are there not houses all the way up to the town of Mardale?—There are some few houses; I have another map showing that. The blue line will show the margin of the lake, when it is raised 42 feet.

635. But are there not houses all the way up?—There are some houses; for instance, there is the Parsonage, but the only other good house is the farmhouse called Measand Hall.

636. Will not the Dun Cow inn be covered?—No, you will see that the hotel is higher up.

637. The whole of this area covered blue will be covered, will it not?—Yes, that area amounts to 370 acres which will be submerged.

638. Do you know the width of the cultivated ground on the small farms there?—About 10 chains, or 220 yards.

639. Then I presume your scheme contemplates the purchase of all the interests affected within the blue line?—Yes.

640. Have you made an estimate of the cost?—Yes, I have. You may recollect the little romantic church there, and it will give you an idea of how high the water would come when I tell you that its surface would be about 8 feet below the entrance of that, Mardale church.

641. On the south-eastern side you simply encroach on the forest?—Yes.

642. The compensation would be slight on the south side, but on the western side it would involve, would it not, the purchase of all the houses and land affected by the lake, including 370 acres?—Yes, of the whole of them.

643. What is your estimate for that?—I have estimated 370 acres of mountain land at 75*l.* an acre, and then I have for rebuilding houses put down 6,000*l.*, which I make up in this way: 1,000*l.* for rebuilding Measand Hall, 1,000*l.* for rebuilding the Parsonage, and for five cottages and small farmhouses I have put down 200*l.* each, amounting altogether to 3,000*l.*, and I have then 3,000*l.* to spare.

644. When you speak of rebuilding, you take away their land, and you take the houses up into the mountain; it would be a question of destruction, would it not, rather than of rebuilding?—You would have to pay for the houses in one shape or another, either by rebuilding or by paying the money.

645. Are you not taking the land on which the houses are built?—Yes, certainly.

646. What is the whole amount of your estimate for the Haweswater reservoir?—The total is 73,500*l.*

647. Does that include your dam at the lower end?—Yes, it includes everything. There are 127,500 cubic yards in that dam; that I take at 2*s.* per cubic yard to cover puddling, pitching, and soiling, &c., which is a high price, and that amounts to 12,750*l.*

648. (*Chairman.*) Could you furnish us with a statement first of all of the general result, and then of the mode by which you have arrived at that general result, together with the details?—Yes, I shall be happy to do so.

649. (*Sir J. Thwaites.*) I understand that by means of this dam increasing the height of the water 42 feet, you propose to store a sufficient quantity of water to compensate the river Lowther?—Not only to compensate the river Lowther, but also to act as compensation on the river Eamont, in fact, to act as compensation for the whole of the eastern portion of the scheme. The Thirlmere compensation would be separate.

650. Would the discharge be continuous under your plan?—Yes.

651. Then in dry weather you would have, would you not, a larger flow of water down the Lowther than there is at the present moment?—Yes, very much more; probably double in volume.

652. Though you deprive them of the benefits of the storm floods you would give them a daily average beyond that which they have now?—We deprive them of the flood water, but in lieu of that we double their summer supply.

653. You are probably aware that they are making arrangements in that river for the salmon to pass up?—The only arrangement that I am aware of is that at a place called the Eel Coop, on Haweswater Beck, half a mile below Haweswater. About 18 months ago they were erecting a salmon stair, but up to that time no salmon had gone into Haweswater.

654. How do you propose to deal with that question—would not your dam effectually stop the progress of that work?—It would of course prevent the salmon getting up; but with a lake, equally well with an artificial reservoir, there might be means adopted to allow the salmon to get into the lake by a long salmon stair, but at the same time I do not believe that the salmon would go into the lake, because there is no spawning ground adjacent; there are cliffs all round it, and no streams with gravel beds into which the salmon would go for the purpose of spawning, so that, as far as salmon breeding goes, I do not see that the raising of the level of that lake would at all affect the question.

655. (*Chairman.*) Looking at the southern point of Haweswater, I see marked upon that map what appear to be several streams which run into that lake; do you apprehend that those streams would not become spawning ground?—They are quite precipitous—a mere succession of water-falls.

656. (*Sir J. Thwaites.*) You also propose to raise Thirlmere, do you not, to the height of 64 feet beyond its present level?—Yes.

657. And you propose to do that also by means of a dam at the lower end?—Yes, there is a very narrow gorge there.

658. On the right of Thirlmere, between Helvellyn and the Fells is the road to Keswick and Ambleside?—Yes, it runs close to the lake, as you will see by this map (*producing the same*). The existing road will be submerged for a considerable distance. It runs from the high ground down to the level of the lake, and then runs up at the other end, and in lieu of that we propose making a level road along the contour line from one point to the other. The hillside has a slope of about $3\frac{1}{2}$ to 1, or 3 to 1.

R. Hassard, Esq.

14 Feb. 1867.

659. (*Chairman.*) Is the present road a hilly road?—Very hilly.

660. (*Sir J. Thwaites.*) The road along the lake is level?—Yes.

661. Then the new road would have rather a serious inclination would it not?—No, it would be a dead level from one end to the other.

662. (*Mr. Harrison.*) You would have to cut the road and conduct it along the steep side of the hill?—Yes, it would be a bench on one side, and a wall on the other.

663. (*Sir. J. Thwaites.*) What acreage of land do you cover by the elevation of the water?—400 acres.

664. What is the length of Thirlmere lake?—Nearly four miles.

665. (*Chairman.*) Do you mean that the lake is four miles, or the ground which you will occupy?—The ground which will be submerged. The lake is about $2\frac{1}{2}$ miles at present, but with the ground which we propose to cover with water it would be about $3\frac{3}{4}$ miles in length, and there would be 400 acres of land submerged.

666. (*Sir J. Thwaites.*) You have made, I presume, an estimate of the property which you destroy all along the border of Thirlmere?—Yes, the total estimate for that reservoir is 83,000*l.*

667. Does that include the dam, and compensation for land and houses?—Yes, it includes everything.

668. How many acres of land do you take?—Four hundred acres.

669. At what rate?—At 75*l.* per acre, which amounts to 30,000*l.*, then I have put down for rebuilding houses 8,000*l.*

670. Some of this land is very valuable is it not?—Some of it is valuable, but a great deal is very poor indeed. You may see from the map that the nature of the land coming down on the eastern side is bare rock.

671. But when you approach the lake, you get some very valuable meadows?—Yes, but the average value would not be more than 75*l.* per acre, which I put it at.

672. How many houses do you remove?—There is one house called Armboth, which is a very good farmhouse, then there is a small parsonage near the church, and there are 18 cottages and small farmhouses, which are of a very ordinary description. As to Armboth, I have allowed 1,500*l.* for rebuilding it. The total amount for that reservoir is 83,000*l.*

673. Now going on to Ulleswater, I think that for reasons given by Mr. Hemans, you only propose to raise it five feet?—Virtually it would be raised only five feet above its mean winter level, or above the ordinary level of the autumn, but two feet above the extreme winter level.

674. I understood Mr. Hemans to say that it would be practically 5 feet above the average winter level?—That is so.

675. Are you aware that on the banks of this lake there is very valuable property?—There is some very valuable property there.

676. Would the increased height of the water submerge any part of that property?—A very small portion indeed.

677. Can you describe the portion which would be submerged?—Yes, I have a map which will show that. The points on the map which you see coloured represent the points where the existing roads will be submerged and new roads will be made. A great deal is bare rock. There is very valuable property at the Patterdale end, but that we shall not submerge.

678. What do you mean by colouring it green?—This stream, named Grizedale Beck, which comes down from the upper part of the valley, now receives the drainage of this portion which is coloured green, and those are meadows which are submerged in winter, probably for two-thirds of their extent. We propose to divert this stream by a watercourse in the position described on the map, taking Goldrill Beck also, and constructing a small catchwater drain on the eastern side of the valley, which will intercept all the water which now flows into that lake at its southern extremity. We then put a bank across the top of Ulleswater, a small bank, probably about 7 feet or 7 feet 6 inches in height, which will keep the portion coloured green secure from the effect of floods from the water backing up from the lake. Very near to the south end of the lake you will observe our eduction aqueduct towards London, the first portion of which is open, and into that would drain the rainfall which would be precipitated on that portion of land which is coloured green.

679. In future you would prevent that which now occurs, namely, the flooding of the portion coloured green?—Yes.

680. (*Mr. Harrison.*) Do you put your catchwater drains at such an elevation as would carry that water to the highest level of the lake?—Yes.

681. (*Sir J. Thwaites.*) At what point do you intercept the washings from the lead mine?—We intercept the washings from the lead mine at Glenridding, at the lead mine itself, and we propose carrying it by a line of iron pipes until it would be discharged into the River Eamont beyond Ulleswater. The cost altogether for intercepting that mining drainage I have put down as at 35,000*l.*

682. (*Chairman.*) What powers will you have for taking this water from that spot into the river Eamont; would not those who live on the river Eamont object to having this water, which you consider too bad to go into the lake, being sent into the river Eamont?—It first goes into the lake, and then into the river Eamont, at present.

683. You would take it by a more direct course, and it would be in a more polluted state when it got to the river Eamont?—No, it would be in precisely the same condition as when it left the crushing mills.

684. When it got to Ulleswater, by your plan, it would be much more diluted than it is at present?—The carbonate of lime, for it is not lead, is now precipitated in the lake all round the mouth of Glenridding Beck, which is the stream coming down from the lead works.

685. Are we to understand you to say that the water, when it reaches the river Eamont, would not be more polluted by your method than after it left the lake, as at present; it would surely be more mixed?—Yes, I should think it would; but it must go somewhere, and the quantity of water which it would be mixed with in the river Eamont would be very large indeed.

686. If, as at present, the people on the river Eamont can tolerate this water, bad as it may be, because it has to pass through Ulleswater, and in its course through the lake is mixed with a great body of water, might it not happen that when they received the water by your method it would be in a very much worse condition, and so injure them very materially?—It would be diluted with such a large quantity of water that I think it would be scarcely perceptible.

687. If I understand your plan rightly, that water would not be diluted at all till it reached the river Eamont?—It would be diluted by a very large quantity of compensation water.

688. You state that the river Eamont would be compensated, but it would reach the river Eamont by your plan minus the dilution of the whole of the lake Ulleswater?—Yes, certainly that is the case, no doubt.

689. (*Sir J. Thwaites.*) When it is discharged at the top of the lake it gets into a comparative state of rest and precipitates the polluting matter, but if you carry it down this channel, of course from the flow in the pipe it would not precipitate at all?—It would be delivered into the river Eamont in a more concentrated state.

690. (*Chairman.*) When the water reaches the river Eamont, although it might be imperceptibly impregnated or mixed with lead now, it would be perceptibly so by your scheme?—The water was very carefully tested for lead, but not the slightest trace of lead could be found in it. The colouring matter is carbonate of lime, and not lead.

691. (*Sir J. Thwaites.*) That would affect the fish, would it not?—I saw a man standing and wading in the lake up to his knees at the mouth of that burn, and I said to the boatman, "Is it possible that the man is fishing; surely no fish can live there?" but he said that it was one of the very best places for trout in the whole lake, so that as far as the fish were concerned it did not appear to affect them.

692. This dam in the upper part of the lake is to prevent, is it not, the water which you raise flowing over that land coloured green?—Yes.

693. You will have to take some property on the north-west side of the lake; have you formed an estimate of the expense of that?—I have.

694. Apart from your structural works?—Yes.

695. Can you give us that estimate?—Yes. The total estimate for that, with damage and compensation, is 100,000*l.*; the land, works, and eduction apparatus would be 78,080*l.* The land submerged would be 76 acres, a part of it valuable land, and a part of it being bare rock and mountain.

696. In this case you would have to divert the road?—Yes.

697. That is mere forest, and it would be no very serious expense there?—No, it would not, until we got down to a place called Hallsteads.

698. Then I understand that for compensation for houses taken and for lands submerged, your estimate is 100,000*l.*?—100,000*l.* is the whole, including everything.

699. (*Mr. Harrison.*) You stated 70,000*l.* for the dam, did you not?—The land I have estimated for at 80*l.* per acre; there are four miles of altering roads, such as are shown here, which I take at 2,500*l.* per mile. There is an embankment, which is a very small thing, at the lower end, at Pooley Bridge, which would be a weir, and it would cost 2,000*l.*; and eduction pipes and valves, the eduction apparatus for drawing off the water for the supply of London, I take at 60,000*l.*, making a total of 75,080*l.*; and to that I add the difference between 75,080*l.* and 100,000*l.* for any additional compensation that may arise.

700. Can you state the height to which the water would be raised by the winter floods, or floods at any time?—By the winter floods now it is raised, from the marks which were pointed out to me, to a height of 483 feet above the Ordnance datum.

701. Can you state how high it would be raised beyond the height of your 5 feet by a fair average flood. You propose to raise it 5 feet above the winter average, that would give you 5 feet increase, what height beyond that will the floods swell it?—From the marks which were pointed out to me an extraordinary flood would rise 3 feet above that.

702. That would be 8 feet above the winter average?—No; 3 feet above the winter average.

703. Then your 5 feet above the winter average would take it 2 feet above the present highest level?—Yes. I was asked a question with relation to Mr. Marshall's house at Patterdale. The level of the ground at his hall-door is about 67 feet above the ordinary winter floods; with the raised lake it would be 65 feet above; his grounds wouldnot be touched at all.

704. (*Chairman.*) That is with regard to the three reservoirs which are to be the source of your supply for London?—Yes, London is intended to be supplied from both Thirlmere and Ulleswater, and very probably some small portion of the supply might be derived from Haweswater also.

705. Will you now state to us how you propose to supply Thirlmere and Ulleswater; because, if I gathered rightly from what Mr. Hemans stated yesterday, you first of all gather the water in the Haweswater district, then you take it from there and put it into Ulleswater?—Only the residue of it.

706. Having, first of all, made the reservoir, and filled Haweswater with water, will you state what you do with that water?—A certain fixed quantity, which has been estimated as equal to 9 inches of rain over the district, would be drawn off from the north end of Haweswater, and passed down the stream daily throughout the year in equal quantities. That is for compensation, to be passed down the river Lowther to a point about a mile below Lowther Castle, and there a gauge weir would be fixed, and a certain quantity passed down the remainder of the river Lowther till it joins the river Eamont below Brougham Hall.

707. The gauge weir, you say, would be fixed below Lowther Castle; would that gauge weir prevent fish from coming up?—No, it would be a very low affair, probably not more than 4 or 5 feet in height, and an ordinary fish stair might be applied. The river Lowther would then carry off each day not only the quantity of compensation water which was due from Haweswater, but it would also have to carry off the flood water which would be due to the area lying below those catchwater drains and the eastern side of the watershed, and that quantity of flood water might of itself at times very much exceed the quantity of water which would be due to the compensation in the river below, and therefore all, except the portion that might be fixed on as compensation, would be carried round by a conduit to Pooley Bridge, where a further quantity, such as might be fixed upon as compensation, would be delivered into the river Eamont and passed down it as compensation water, and the residue, if any, would be passed into Ulleswater.

708. (*Mr. Harrison.*) The lower level where you propose to put the weir is still above the level of Ulleswater, is it not?—Yes, the conduit from the river Lowther to Pooley Bridge would have a fall of 2 feet per mile from one point to the other.

709. (*Chairman.*) That is the mode of carrying the water from that district into Ulleswater?—Yes, that is the mode of dealing with Haweswater and its drainage area.

710. And compensating by the means which you describe the river Lowther and the river Eamont?—The water of the river Lowther is of excellent quality, still, being the least pure of the district it is proposed to use it for compensation and apply the purer water for the supply of London.

711. Will you now describe what you do at Thirlmere?—Thirlmere Lake has naturally a small drainage area. It is admirably suited for converting into an immense reservoir, but the area of land naturally draining into it is small, therefore it is necessary to bring water to it from other localities, and in order to effect that catch-water drains are projected towards the Borrowdale side, as indicated on the map. Those catch-water drains are all on the western side, at the foot of the table land which slopes towards Borrowdale. From below the catch-water drains, down to the Watendlath River into Borrowdale, the ground is very precipitous, but those catch-water drains are upon the table land at the upper side of the cliffs, and they would carry round into Thirlmere the waters of Cold Barrow Fell, and Bleaberry Fell. All those catch-water drains, with the exception of the one from the river Lowther to Ulleswater, are laid out with a fall of either eight or 10 feet in the mile, and they are open cuttings following the contour line, or nearly following the contour line of the district.

712. Have you prepared any sections of your works?—Yes, I have sections of all the works; for instance, here is a section (*producing the same*) showing the mode of construction, also of those catch-water drains. The probability is that many of them will not require puddling, as indicated there on the section, but they are all estimated as if they will; there will be a stone facing with a clay backing. Here is also a map (*producing the same*) showing the way in which they were projected from the contours; for instance, one thin line represents an elevation of 900 feet, another represents an elevation of 800 feet. The level of the catch-water drain at that point is 855 feet, the 850 feet being nearly equi-distant between the two contours. On the northern side of Thirlmere it is intended to construct a catch-water drain of precisely similar construction to what I have just shown, running along the hill sides, and following the contour with the

R. Hassard, Esq.

14 Feb. 1867.

exception of a point where a bit of tunnel would be necessary (the tunnel being a mile in length), delivering into Thirlmere at its north-eastern extremity. That catchwater drain would intercept the waters of Barrow Beck, Trout Beck, and Mosedale Beck, and also the water flowing from Matterdale Common and the hills called the High Fells. Then eventually, when the demand amounts to 250,000,000 gallons per day, it might be necessary to construct another reservoir, for which there is an admirable site, a purely artificial reservoir below Thirlmere, for the purposes of compensation. But in the first instance that would not be necessary at all, as both the compensation water and the water for the towns' supply keeping up Ulleswater could be drawn off from Thirlmere. The compensation water would be for the supply of some mills and pencil factories and bobbin mills, which are situated on the river Greta, above Keswick. Then having got the water into Thirlmere, we construct an open conduit for some portion of the distance, running northwards, and from that into Ulleswater there would require to be a tunnel, and that tunnel would be eight miles in length, but the extreme depth of the shafts would not exceed 400 feet, and it only becomes a question of additional shafts. Except as regards the increased length, that would be quite similar to the tunnel which has just been constructed for the Dublin waterworks. (*The witness produced and explained a section of the tunnel.*) It is 12 feet high and 12 feet wide, and falls 2 feet in a mile.

713. (*Sir J. Thwaites.*) Is that slate or rock?—It is clay slate in that portion of the district. In one spot near the Ulleswater end of it the old red sandstone appears for some very short length.

714. You will line the whole of this of course?—Yes, with the stone excavated in the construction of the tunnel itself. I constructed a very difficult tunnel in Ireland for Mr. Hemans in that way. It was through the same rock, and we lined it entirely with the excavated material.

715. (*Chairman.*) What is the total distance?—The total length is 8 miles of tunnel, over the whole length of which shafts can be sunk.

716. The extreme depth at any one point is 400 feet?—The maximum depth is 400 feet.

717. (*Mr. Harrison.*) You would not propose to put down the same number of shafts that you show in the section, would you?—We should probably put down more shafts, but the Kirkstone Pass tunnel is the key of the whole work, and there would not be any necessity for having this tunnel completed before that one was finished—it becomes a mere question of time. The question of the time of completion is, of course, regulated by the number of shafts; if it was to be done in two years a larger number of shafts would be necessary. We have put them down at three to the mile, with which number it could easily be completed in the time that would be necessary for the construction of the Kirkstone Pass tunnel.

718. (*Sir J. Thwaites.*) Have you made a calculation as to the cost for severance of land, where you carry your open aqueduct?—It is included in the cost of the catchwater drains themselves.

719. (*Chairman.*) Will the details appear in the statement which you have put in?—I shall hand in all the details.

720. (*Sir J. Thwaites.*) I presume that for agricultural purposes you have bridges over those aqueducts?—The occupation works were taken, I think, at 250*l.* a mile, for bridges across the aqueduct. The district is mostly sheep farms. Those catchwater drains are proposed to be fenced, and that is included in the estimate.

721. (*Chairman.*) When you talk of fencing, what descripton of fence do you propose to put up along those catchment drains?—The ordinary fences of that country, which are dry stone walls.

722. About what height?—About 4 feet 6 inches in height.

723. Do you think that a 4 feet 6 inch wall would keep those mountain sheep within bounds?—I do not think that the sheep would do any harm to the water.

724. I do not know whether the Cumberland sheep are like the Highland sheep, but no 4 feet 6 wall would keep Highland sheep within bounds?—There are not many sheep in the locality. What agricultural produce there is is sheep, but it is so bare that really there are not many sheep over the greater portion of the district.

725. But the other drains which you propose to preserve by fencing would, I conclude, be fenced against something which might be expected to happen?—I estimate for fencing, but it scarcely need have been considered.

726. (*Sir J. Thwaites.*) The sheep would not jump into the water, I presume?—No; I do not think that the quality of the water will be affected one way or the other.

727. (*Chairman.*) The fences would be dry stone dykes, I presume?—Yes, dry stone dykes.

728. Might you not save yourself the expense of putting them up?—I do not myself think that they will be required, although I have estimated for them.

729. You propose to get to Ulleswater by a tunnel, which will be eight miles long?—Yes.

730. Now will you take us on further until you get to the southern point of the lake?—From the southern point of the lake the water is proposed to be drawn off for the use of London, and from that point to Stockport, which is a distance of 110 miles, we have the sections of the course of the aqueduct carefully prepared, and shall be happy to submit them to the Commission. As soon as you get out of Westmoreland, and a short distance south of Ambleside, the whole of Lancashire is contoured to elevations of 25 feet, and that enables sections as nearly approximate as possible to what would actually occur in practice to be plotted, and there can be no essential difference between the sections which we have prepared and the sections which would be the sections of the works actually constructed.

731. (*Sir J. Thwaites.*) Your main line of aqueduct to the metropolis would commence at the upper end of Ulleswater Lake?—Yes, at the south end.

732. And you will be there in tunnel very rapidly?—There is about two miles of open cutting, and then we go by tunnel under Kirkstone Pass, coming out above Ambleside.

733. (*Chairman.*) Will you describe the portion of the ground from Ulleswater to Ambleside?—From Ulleswater to Ambleside, for the first 2 miles, the aqueduct is open cutting; then we get into tunnel, all of which, except $1\frac{3}{4}$ mile in the central portion, is a comparatively shallow tunnel. The total length of tunnel is 6 miles. Then having left that tunnel, from Ambleside onwards, we get into open ground, with occasional spurs of hills, through which we tunnel. Part of that would be covered aqueduct and part of it open. I shall produce sections showing the mode of construction. We cross, then, one or two streams running down, which are crossed by syphon pipes 8 feet in diameter, of the same material as was shown yesterday by Mr. Hemans and lined with Portland cement. There is very great economy in using those large pipes, which I shall explain by-and-bye.

734. What is the depression of the pipe at Bridge Lane?—There it would be about 140 feet. From Bridge Lane onwards the same mode of construction is followed, partly open aqueduct and partly tunnel, until we get to Staveley, where there is another depression of about 150 feet. There are some watercourses, and we estimate for bridges over all those; and from that onwards the same mode of construction continues.

735. Is that a stone aqueduct or a girder?—In passing round those hill sides the works are proposed to be constructed of the ordinary stone of the country, the excavated trench being made water-tight by a backing of concrete in hydraulic lime. I have here two sections of open aqueduct (*producing several sections*), one with a fall of 4 inches per mile, which

will give a velocity of 109 feet per minute, and a discharge of 28,340 cubic feet—28,000 cubic feet per minute, representing 250,000,000 gallons per day. The next is an open aqueduct, with a fall of 6 inches per mile, which has a velocity of 128 feet per minute, and a discharge of 27,702 cubic feet per minute, being so nearly 28,000 cubic feet that I did not think it worth while altering the design. The third is a section showing a covered aqueduct, with a fall of 4 inches per mile, the velocity of which is 106 feet per minute, and the discharge 28,514 cubic feet per minute. The fourth is a section of covered aqueduct, with a fall of 6 inches per mile, which gives a velocity of 127 feet per minute, and a discharge of 28,575 cubic feet per minute. The fifth section is of a tunnel, which would be 20 feet wide and 15 feet high, with a fall of 6 inches per mile, the velocity of which would be 125 feet per minute, and the discharge 28,240 cubic feet.

736. (*Sir J. Thwaites.*) Can those at any time be under pressure?—Nothing beyond what is due to the depth of the water in the aqueduct.

737. Then they never can be running at the full volume?—They never can. These sections show the covered and open aqueducts near the northern portion of the project, extending as far as Stockport. In some cases you see the word "substructure," which is shown by a green colour; that portion of the aqueduct is proposed to be constructed in this way: it is carried upon arching with a pitched channel backed with concrete, the same in form as the sections which I have just exhibited, and then it is surrounded by an embankment which is made up of the material which has been excavated in the trench on either side of it, and wherever the word "substructure" occurs on that section it refers to this mode of construction; where "arched aqueduct" is given, this is the mode of construction proposed to be adopted—a raised aqueduct carried on arches—in fact it is built and carried upon a viaduct, and the same mode of construction is carried out throughout. Each of those depressions on the section is crossed in the same way by iron pipes.

738. What is the width of the depression which is marked at the 22nd mile on the deposited plan?—About five furlongs.

739. What is the depression?—The depression is something about the same as I gave before—about 140 feet. Between the 26th and 27th mile the section represents an aqueduct carried upon arches, and those are put on merely to show that that mode of construction is contemplated. These would measure about 120 or 130 feet each, whereas they would in reality be only 25 or 30 feet each arch.

740. What will be the length of that aqueduct?—That raised portion on arches would be about 26 chains, or about 572 yards, and the same modes of construction are carried on all through. I see between the 30th and 31st mile that there is another small raised aqueduct. When we come to the 33rd mile, at a place called Lupton Beck, there is an inverted syphon a mile in length.

741. Is the depression about the same?—Probably a little more, about 150 feet I should say at that part. Then the same mode of construction is carried on until we arrive at the river Keer, near Burton-on-Kendal. Between the 37th and the 38th mile there is an inverted syphon of a mile and five furlongs in length.

742. (*Mr. Harrison.*) In passing that spot you do not appear to give more than three feet of fall?—It is calculated for a fall of 1 foot 8 inches per mile. I may mention that there is very great economy in using those large pipes. For instance, three lines of 8-feet pipes, with a fall of 1 foot 8 inches per mile, will discharge as much as ten 4-feet pipes with a fall of 5 feet per mile. The same velocity may be obtained by the water in passing through a large pipe with a small fall as there is in its passing through a small pipe with a large fall.

743. That is one of the reasons why you adopted a wrough-iron pipe with a heavy pressure of 300 feet, in order to get greater strength?—Yes, and also from motives of economy, because we could lay down three lines of 8-feet pipes to convey 250,000,000 gallons of water per day, at a price of nearly 40,000*l.* per mile cheaper than it would take to lay down 10 lines of 4-feet pipes with a fall of 5 feet per mile. In each of those cases I may say that we have assumed the actual discharge of those large pipes at 33 per cent. over the theoretical one, Mr. Bateman having found in the pipes which he laid down at Glasgow, which were 4-feet pipes, that they discharged fully 61 per cent. more than their theoretical quantity. In making that statement I have taken the 4-feet pipes also at 33 per cent. more than the theoretical discharge, and I have added that in each case. That takes us down to 5 miles from Lancaster, and then at a point about 5 miles from Lancaster we can supply that town with water. Onwards from this the work is of a very light nature, with the exception of one or two gorges which are passed by raised aqueducts. Then from the 64th mile onwards there is a great deal more of iron piping.

744. (*Sir J. Thwaites.*) Is the 64 miles measured from the head of Ulleswater?—Yes. The same mode of construction continues, but owing to having to pass a great many depressions a great deal of it is iron pipes. At the 66th mile it is opposite the town of Preston, and from that point at the village of Longridge water might also be supplied. We have about 4½ miles of piping crossing the river Ribble, with an extreme depression of 340 feet. In such portions of the work as tunnels and raised aqueducts, which are the most expensive parts of the project, with the exception of the iron pipes, the fall is kept at six inches, and where it is of comparatively cheap construction, such as may be indicated between the 71st and 72nd mile, the inclination is kept at four inches to a mile. I may mention that the velocities which water would attain in those conduits are something like 20 per cent. greater than the velocity in the aqueduct conveying water from Loch Katrine to Glasgow, and about 20 or 25 per cent. greater than the velocity in the conduit lately constructed for the supply of Aberdeen. It may appear strange that a high velocity can be got by a small fall, but if you will allow me, I will explain that to the Commission in a very few minutes, and I trust that I shall be able to make it very clear. The velocity of water in any aqueduct depends upon two conditions, it depends first of all upon the ratio which the sectional area of the fluid bears to the wetted perimeter or surface with which it is in contact, and secondly upon the fall. The ratio of the section to the wetted perimeter or frictional surface is technically called the hydraulic mean depth, and that is very much greater in large aqueducts than it is in small ones. For instance, here is a rectangular section of a conduit 12 feet deep and 12 feet in width (*producing the same*), and the sectional area of that will be 144 square feet. The wetted perimeter is 36 feet, and 144 divided by 36 will give the quantity of 4, which is the hydraulic mean depth of that conduit. We will now take a small conduit, 3 feet square. The sectional area of that will be 9, and the wetted perimeter of that also is 9, which divided into 9 is equal to 1; therefore in the one case the hydraulic mean depth is represented by 4, and in the other it is represented by 1, and it follows that in the larger conduit, which is 12 feet square, the water would attain the same velocity with a fall of 1 foot per mile, as it would in the smaller one with a fall of 4 feet per mile, or in other words, the velocity which water will attain in a 10-feet culvert with a fall of 2 feet per mile will be precisely the same as the velocity in a culvert of 2 feet diameter with a fall of 10 feet per mile. It is in that way that the velocity is high with a small fall, in fact, the velocities in those conduits are as great as it would be safe to use, and if I had a greater available degree of fall at my disposal I should be afraid to use it excepting for iron pipes. We have just had a very notable instance, in the case of the large aqueduct of the Ganges Canal, 1,200 miles in length; the engineer who planned that designed it and carried

R. Hassard, Esq.

14 Feb. 1867.

it out with a fall of 15 inches per mile, and the result is that the aqueduct has nearly torn itself to pieces. It has produced, instead of an equable stream, a destructive torrent, and they are actually at the present moment obliged to build a number of barriers in the shape of weirs across to stop it and preserve the aqueduct from destruction.

745. (*Col. Harness.*) Is not the part where it is cut through of the worst possible material?—I do not know; I can only speak from what I have heard.

746. (*Chairman.*) Will you proceed with your description of the course of the aqueduct?—At the 85th mile we pass immediately below the Rivington reservoir (which supplies Liverpool), at an altitude of 40 or 45 feet above their pure water basins, so that a supply might be given to Liverpool at that point most advantageously. The same mode of construction is carried on until we get to just immediately south of Bolton, and from that until we get to Stockport, with one or two small intervals in the shape of relief tanks, covered over, the aqueduct would consist of piping, and would be piping till we get to about 5 miles south of Stockport, where the ordinary construction would recommence. I may say that from a point south of Bolton, that is from the 91st to the 96th mile, is the only place in the whole line of aqueduct where any coal workings have occurred.

747. (*Mr. Harrison.*) So far your work has been all laid out from the Ordnance surveys, and not from actual levellings?—Precisely. Out of the first 110 miles there are $16\frac{3}{4}$ miles of tunnel; there are 4 miles of covered aqueduct, $46\frac{1}{2}$ miles of open aqueduct, 10 miles of aqueduct carried on substructure or on arches, as I have explained, and $32\frac{3}{4}$ miles of iron pipe. Those constitute the different parts of the 110 miles. The iron piping is laid out for the supply of the first instalment of 175,000,000 gallons per day, but in the estimate of 13,500,000*l.* for the total scheme we have included the additional pipes to bring in the full supply of 250,000,000 gallons.

748. (*Chairman.*) Have you calculated in the expenses the supply of the pipes to the various towns on the road?—No, because I look on that as a matter which will pay for itself.

749. Do you set off what money you would get for the water against the cost of conveying it?—That is a question which I did not take into consideration, because I looked at it merely in the light that if it was worth while for any town to take water from us it would be worth our while to construct works to supply them, for we pass in every case almost close to the towns, or at least within easy distance.

750. You are 25 miles from Liverpool, are you not?—Yes, but we are only a quarter of a mile from their pure water basins, into which we should deliver the water. Here is a drawing (*producing the same*) showing a tank at the end of each of the three lines of pipe, and those pipes are furnished with sluices by which the water can be shut off from any one of them at any time, and they can be emptied at the lowest point and examined internally, and can be traversed from end to end. In addition to the ordinary valves they are proposed to be furnished with what we term momentum gates, and in the event of a fracture or accident happening to any of those pipes those gates would close themselves, so that the only damage which could ensue would be by the water which is already in the pipe escaping, and the supply would be shut off. There is a pendulum hung near the mouth of the pipe, and it is so adjusted that it is not moved by an ordinary current of water passing through, but in the event of a fracture, which would bring a rush of water into it, the valve would assume the position shown by the red line, the gates would then close, and the supply to the pipe would be then shut off.

751. (*Mr. Harrison.*) Is the 110th mile the point to which the contour lines enable you to carry your sections?—Yes, we have only, of course, the one-inch survey beyond that point, but I have brought with me maps which show the levels which we have got from canals and from railways, and from different other sources, which enable us to fix with great accuracy the line of the aqueduct, so that the deviation from that line would be comparatively of a very trifling nature. This small Bradshaw's map which I produce will show the assistance which we have derived from the Ordnance lines of levelling, the blue lines indicating the main Ordnance lines of levelling, which for a considerable distance pass almost along the line of the aqueduct, and cross it at two other points. Stockport is the point where I described that the contour Ordnance maps end, and from thence the line takes a route passing outside the Staffordshire coal field. Those heights which are indicated in red are all heights along the line of aqueduct, which have been ascertained from the Ordnance or from other lines of levelling.

752. How far are you at the nearest point from the Staffordshire coal field?—About half a mile, and it can be kept further if it is necessary.

753. Do you consider that half a mile is a sufficient distance to prevent the water from being impregnated?—Yes, it is on a different geological formation.

754. Will you tell us what the geological formation is at the nearest point to the Staffordshire coal field through which the aqueduct will be carried, within half a mile?—The geological formation at that point is the new red sandstone. I may point out that immediately after, about four miles to the east of Bolton, where I described that there have been some coals found, there is a line of permian marls and new red sandstone lying to the east of Manchester, along which the line of aqueduct is carried. There is a band of permian marl intervening between the red sandstone and the coal measures. From Macclesfield onwards the line passes to the west of the Potteries, passing round the south-western portion of the Staffordshire coal field. There the formation is permian marls and new red marls, lias shales, limestone, oolites, shale, chalk, the Wealden clay, the Oxford clay, and so on (*describing the same on the map*). From the Potteries we proceed onwards, in a south-easterly direction, along the table-land known as Needwood Forest, and and we cross the river Trent about four miles to the south-west of Burton-on-Trent, the elevation of the aqueduct itself there being between 340 and 350 feet. The river itself is 160 feet, and there would be a depression consequently there of about 200 feet. Having crossed the river Trent we get upon the table-land of Charnwood Forest, and pass onwards to the district traversed by the Ashby-de-la-Zouch canal, and to give the Commission a notion of the nature of that part of the country, I may say that from Ashby-de-la-Zouch to Rugby, a distance of about 55 miles, measured along the canal, it is in one level reach. From Rugby onward towards London the line of aqueduct follows in a great measure the route of the Grand Junction Canal and the London and North-western Railway, and it terminates in regulating reservoirs to be constructed north of Edgeware, at an elevation of 220 feet above high water, which is considered ample for London; and from that point we propose to distribute to the existing reservoirs of the existing waterworks, and utilize as far as possible the present means of distribution. The districts supplied by the works of the various water companies in London may be looked upon as contiguous cities, and any attempt to introduce a new system altogether would be attended with great unnecessary expense, and lead to the uncalled for abandonment of a great portion of the present works. From those regulating reservoirs the service reservoirs of the existing companies will be supplied, so as to avoid as far as possible the abandoning or not making use of the present means of distribution.

755. Now will you describe the geological formation of the gathering ground, beginning at Ulleswater?—The gathering ground of Ulleswater is the Silurian slate, except one small portion of old red sandstone which appears at the north end of Ulleswater. There is a very

small portion, about six miles long by two miles broad, that is about 12 miles out of 180, which is old red sandstone, the rest being Silurian slate.

756. (*Mr. Prestwich.*) Do you suppose that you can convey the water without lining the aqueduct?—It is probable that in the construction of a great portion of the open aqueduct it may be constructed without a lining, but we include the cost of lining it all. The aqueduct then traverses the Silurian shales and sandstone. For a short distance of about two miles near Kirkby Lonsdale it passes through the lower limestone shales, it then enters the millstone grit, and continues in the millstone grit, with one or two exceptions, where crossing the valleys of rivers we meet with the upper limestone, but as the depressions would be crossed by iron pipes, the geological formation is not a matter of much importance.

R. Hassard, Esq.
14 Feb. 1867.

757. There are no parts of the geological formation of a nature to present any engineering difficulty?—No.

The witness withdrew.

Adjourned to Wednesday next, at half past 11 o'clock.

Wednesday, 20th February 1867.

PRESENT:

HIS GRACE THE DUKE OF RICHMOND IN THE CHAIR.

Sir JOHN THWAITES.
Colonel HARNESS.
Alderman Sir BENJAMIN PHILLIPS.
THOMAS ELLIOT HARRISON, Esq.
JOSEPH PRESTWICH, Esq.

RICHARD HASSARD, Esq., further examined.

R. Hassard, Esq.
20 Feb. 1867.

The witness delivered in the following statement:

DATA on which the WORKS for supplying DUBLIN and SUBURBS with water from the river VARTRY were projected by RICHARD HASSARD, C.E., in the year 1858.

The population of Dublin with its maritime suburbs was then about 300,000, and the least quantity of water it was deemed desirable to secure the control of, in the first instance, was 12,000,000 gallons daily; it was, however, held to be indispensable that this supply might be augmented at trifling cost, as the demand for water increased in the future.

Almost all the mountain ranges near Dublin being covered with vast beds of peat, and the streams flowing from them consequently tainted, and being also used largely for mills and manufacturing purposes, it became necessary to seek the supply from some elevated district, free from these objections.

A district in every way eligible was found in the county of Wicklow, although at a considerable distance. The drainage area extended over about 16,640 acres, and was partly of granitic and partly of silurian formation; it contained but little peat and there were excellent sites for the necessary reservoirs.

The water from the district, however, flowing in a southerly direction, it became necessary to reverse it, and carry it northwards to Dublin by tunnelling through an intervening mountain range.

This project possessed the advantage of being able to supply from the main aqueduct, *in transitu* to Dublin, the several fashionable watering-places and suburbs of Bray, Killiney, Dalkey, Kingstown, Monkstown, Black Rock, Booterstown, and Sandymount, situated on the south side of Dublin Bay, and dependent for water on wells and the rain collected from the roofs of the houses.

The only question in doubt was the rainfall, and on this much discrepancy of opinion existed. The rainfall in Dublin, at an elevation of about 100 feet above the sea, for the 16 years from 1837 to 1852 inclusive, not averaging more than 29 inches, whilst for the year 1847 it was only 24 inches; it was obviously therefore unsafe to take the mean of three consecutive dry years at more than 27 inches.

No gauges having been kept in the Vartry drainage area, the only mode of determining the additional amount of rain due to the greater mean elevation of the Vartry district (960 feet) was by investigating the results ascertained in other places to be due to this cause.

These left no doubt that an additional quantity of about 30 per cent. might fairly be relied on, thus bringing the mean rainfall of the Vartry district, in three consecutive dry years, up to 35 inches. (This was borne out by the returns of a gauge kept in the vicinity, but the existence of which was not known at the time.)

Deducting 14 inches for loss from evaporation and absorption there remained 21 inches as applicable for town supply and compensation, and deducting one third for compensation, this left, for town supply, 14,480,218 gallons daily.

The supply can at any time be largely increased by extending the works in the direction of Lough Dan and Lough Tay.

758. (*Chairman.*) Is there any explanation which you wish to give with regard to any part of your former evidence?—Yes; some matters escaped me at the time, which I should like to refer to to-day. With regard to question No. 684, the purport of the question was whether the parties living on the river Eamont would not get the drainage from the lead mines in a more concentrated form than at present, by the means which are by our plan proposed to be adopted, and I answered that they would. But I should wish to extend that answer, and say that by constructing settling tanks at the north end of Ullswater, the drainage from the lead mines might there undergo precipitation and be delivered into the river Eamont in a state not more objectionable than at present. In fact, it would be so largely diluted with water and so comparatively pure by the process of precipitation that no ill effects would arise.

759. (*Sir J. Thwaites.*) I understood that your first object was to intercept that water from flowing into Ullswater so as not to contaminate the source of your supply?—Yes.

760. You propose to bring it by means of pipes down to Pooley bridge and then to discharge it into the river Eamont?—Yes.

761. His Grace's question was, whether if you were to discharge it into a smaller volume of water than into the lake itself it would not injure that river. I understand your amended answer to be that you propose to construct settling tanks at the north end of the lake and then after precipitating the colouring matter, whatever it may be, to allow the clear water to flow off into the river Eamont?—Yes, although I believe that the injury which would be done to the water in the lake if it was discharged into it towards its northern end at a considerable distance, say three or four miles, from the point where the water would be drawn off for London would be so little that the water would be innocuous, yet at the same time I should prefer passing it into the river Eamont at Pooley bridge. The town of Penrith which is now supplied by pumping water from the river Eamont immediately adjoining could then be supplied with purer water than it gets at present by piping water from Ullswater.

762. It is a considerable distance, is it not, from

R. Hassard, Esq.

20 Feb. 1867.

Ullswater to Penrith?—It is about 4½ miles to the point where they pump, it would not be a serious expense; they take the water from below the bridge.

763. And before it joins the Lowther?—Yes, before its confluence with the Lowther.

764. (*Chairman.*) That would be an addition to your present scheme?—It would be a small additional expense, but it is fully provided for in the contingencies that we have estimated for.

765. Was there any other point which you wished to clear up?—Yes; relative to the construction of the open conduit, I omitted to mention that wherever a public road crosses the conduit we have allowed in our estimate for covering it 50 yards on either side of the centre of the public road, so that wherever it would be crossed by public traffic it would be to all intents and purposes a covered aqueduct.

766. (*Sir J. Thwaites.*) You mean 50 yards in addition to the bridge?—The bridge or covered part of the conduit would be 100 yards in length.

767. You would fence the bridge off a reasonable width, would you not?—Yes, we should fence the bridge off for the width of the present road, and cover the culvert 50 yards on either side of the centre of that road up and down the stream.

768. (*Chairman.*) Is there any other point which you wish to explain?—Yes; relative to the mode of drawing off water from Haweswater and from Thirlmere, I mentioned that we intend raising those lakes, I think, 42 feet in the one case and 64 feet in the other, but we intend to draw off the water 15 feet below the present surface of those lakes, and to draw off in both cases by tunnels, so as to avoid the danger of constructing culverts through embankments; there will be tunnels through the rock.

769. (*Sir J. Thwaites.*) And that gives you the holding capacity so far as you are concerned?—Yes, it increases our capacity of storage, and the water would be drawn off through iron pipes laid in tunnels driven through solid rock.

770. Your calculation is based upon the invert of your pipe 15 feet below the present level of the lakes?—Yes.

771. That is not the storage of the lake itself?—No, the lakes are deeper than that.

772. Haweswater is nearly 300 feet deep, is it not?—It is an immense depth, I do not know the precise depth. The quantities of all those reservoirs have all been taken out by cross sections, so there is no question as to their capacity. There is one other matter with regard to which I should like to give an extended answer. His Grace asked me whether I had made provision in the estimate for works for supplying other towns with water, and my answer was that I had not, that the sale of water would pay for itself or something of that kind, but what we should do is this—we should supply water in bulk, we should supply towns adjoining our works with water, and sell it to them all at the same rate at which we should be able to deliver water in London, that is to say, at about 10*l.* per 1,000,000 gallons, or 2·4*d.* per 1,000 gallons, and we should let the towns do everything else after that. We should supply the water in bulk leaving them to do the rest, and to charge any price they liked to their customers or to the inhabitants respectively. It is a very usual way of managing the matter, it is intended to be so done in Dublin at all those places which you see coloured on the map green, as the towns are to be supplied in bulk and the corporations or authorities of the towns then take charge of the distribution.

773. They would, in point of fact, construct their own works?—Yes, such additional works as might be necessary.

774. They would construct them up to your tunnel?—Yes, up to our aqueduct.

775. (*Chairman.*) Would not that be constructing the whole of the works?—Yes, such additional works as were necessary for an extended supply; if they wished to extend their supply in any direction they would have to construct the additional requisite works, as a matter of course.

776. (*Sir J. Thwaites.*) You would merely supply the raw material?—Yes; we should supply it in bulk and let them retail it or distribute it as they pleased.

777. (*Chairman.*) But they would have to store it at those places, would they not?—No; there would be no storage necessary, or a very limited storage, perhaps 3 or 4 days supply to guard against any accident to the works; but the body of water in the aqueduct would be constant, and we could supply day by day the quantity which would be required. The storage would be in the lakes, and the quantity that we should draw off daily would be constant.

778. (*Mr. Harrison.*) If you will be so good as to refer to your answer to question No. 743 in your former evidence, you will see that you say there, "In each of those cases I may say that I have "assumed the actual discharge of those large pipes "at 33 per cent. over the theoretical one, Mr. "Bateman having found in the pipes which he laid "down at Glasgow, which were 4 feet pipes, that "they discharged fully 61 per cent. more than their "theoretical quantity." Is that correct?—It is correct so far as this, that Mr. Bateman stated that there could be no doubt that the pipes discharged a quantity at least equal to 40 to 50 per cent. above their theoretical quantity; but I calculated carefully what they actually did discharge and I fond it to be 61 per cent.

779. You say Mr. Bateman having found that they did so?—So far as that expression goes that is not quite correct. From 40 to 50 per cent. was Mr. Bateman's actual expression, and my calculation gave 61 per cent.

780. Then this statement of yours requires correction?—Yes, certainly.

781. Where do you find that statement of Mr. Bateman's?—It is in the evidence before the Metropolitan Sewage Commission. In his evidence before that Commission Mr. Bateman stated that in the Glasgow waterworks 4 feet cast-iron pipes, with a fall of 5 feet per mile, were calculated to deliver 20,000,000 gallons daily, and that with a fall of 3 feet 6 inches per mile is 61 per cent. more than 16,300,000 gallons which is the theoretical quantity a 4 feet pipe would deliver with that fall. Further on in his evidence Mr. Bateman stated this. He was asked to what cause he could attribute that, and he said that it was owing either to the coating of the inside of the pipes with Dr. Angus Smith's preparation of coal-tar, which rendered them very smooth, or it was because the formula which we have hitherto used for those calculations was made upon a much smaller class of pipe than has been lately introduced; but from whatever circumstance, he said, there is no doubt that those pipes discharged from 40 to 50 per cent. more than their theoretical quantity.

782. Perhaps you are not aware whether that large increase of discharge has continued, or whether, as I believe is the fact, it has been gradually diminishing?—That I am not aware of.

783. I understood from Mr. Bateman that owing to the different state of the pipes, they being in the first place almost like glass from the application of this mixture, from that mixture either decaying or otherwise since the period at which he made that statement, the discharge has gradually been diminishing?—I think it is probable, although I am not aware of the fact. I may observe that the coating of Portland cement, which we propose using inside our pipes, is imperishable, and we believe that it will have precisely the same effect of giving a smooth surface which Dr. Augus Smith's preparation gave in the Glasgow case, and we do not anticipate any diminution of the discharge in consequence of the state of the lining.

784. Will you just refer to the next question, No. 744, in answer to which you say, "I may mention that "the velocities which would be attained in those con-"duits are something like 20 per cent. greater than the

"velocities in the aqueduct conveying water from "Loch Katrine to Glasgow, and about 20 or 25 per "cent. greater than the velocity in the conduit lately "constructed for the supply of Aberdeen." On what basis do you assume that your conduit will discharge at a velocity from 20 to 25 per cent. greater than is obtained in the cases of Glasgow and Aberbeen?—I know that the velocity in the Glasgow aqueduct is from 100 to 105 feet per minute, and I have calculated the velocity in our aqueduct, and it is something like 120 feet per minute.

785. Does not what you are now assuming rather go to disprove the accuracy of the formulæ, which are in constant use, with regard to discharge of water by rivers?—No, there has been no variation found out as regards the discharge of conduits.

786. In that answer you refer, do you not, to conduits?—But that increased discharge in the Glasgow case applied only to pipes under pressure used as conduits; we have assumed no variation from the ordinary formula for conduits lined with masonry.

787. You say, "I may mention that the velocities which are attained in those conduits;" does that mean your pipes?—No, the expression conduits is certainly applicable to both pipes and open and covered aqueducts, but there is no per centage of increase assumed for the aqueducts of masonry; the actual discharge has been calculated and the actual velocity.

788. Does not this rather lead to the assumption that you do calculate 20 per cent.?—No, certainly not; I did not intend to convey that.

789. Will you have the goodness to put that matter quite right?—I say "I may mention that the velocities "which would be attained by water in those conduits "are something like 20 per cent. greater than the "velocity in the aqueduct conveying water from "Loch Katrine to Glasgow." There is only a small portion of the aqueduct from Loch Katrine to Glasgow, which is composed of iron pipes. It is an ordinary covered conduit and tunnel.

790. (*Sir J. Thwaites.*) How do you get that 20 per cent. increase?—It is owing to two causes, as I mentioned the other day. The velocity of the water in a conduit is dependent on two things: it is dependent on the body of water in the conduit and upon the fall, and an aqueduct with a large sectional area conveying a large body of water will convey it at a velocity the same as will be attained by a much smaller culvert with a greater fall. It will be remembered that I said that water flowing through a 10 feet culvert with a fall of 2 feet per mile will have precisely the same velocity as water flowing through a 2 feet culvert with a fall of 10 feet per mile.

791. (*Mr. Harrison.*) You say I "may mention that the velocities which are attained in those conduits," what does "in those conduits" refer to?—By those conduits, I allude to open and covered aqueducts and tunnels, not to pipes; I allude to the whole of the aqueducts excepting the pipes.

792. Then in fact you calculate upon a velocity of something like 20 per cent. greater than the velocities in the aqueduct conveying water from Loch Katrine to Glasgow?—I say that our aqueduct will convey water with a velocity 20 per cent. greater than the Loch Katrine aqueduct does, both being calculated from the same formula. Not the pipes, but the open and covered aqueduct, owing to its large size, will convey the water with a velocity 20 per cent. greater than that which the water attains in the Loch Katrine aqueduct, though the latter has a much greater fall.

793. Your answer hardly conveys the impression that it is 20 per cent. greater than the velocity in the aqueduct, because there is nothing to compare it with; we have not here sections of the Loch Katrine aqueduct, and your answer conveys a wrong impression?—Not so. There are the sections (*producing the same*). The Loch Katrine aqueduct is 8 feet wide and 4 feet deep at the springing of the arch in its ordinary construction, and, therefore, there is a very large amount of frictional surface in contact with the water compared with what there is in our aqueduct, owing to its greater sectional area.

794. You do not mean to dispute the ordinary formula upon which all those calculations are made?—Certainly not.

795. Not in the case of the conduit?—Certainly not. Our calculations, for the open and covered conduits, are based on it. There was one point relative to the construction of the tunnel by which we propose to draw the water off from Ullswater, on which I should wish to make a remark. It was stated, that from the rate of progress which was made at Loch Katrine, it would very likely be a work of a great period of time. I beg to hand in a statement of the progress which has been effected in the Mont Cenis tunnel during the years 1863, 1864, and 1865. In the year 1863 at the Bardonnéche end, that is the Italian end, the rate of progress averaged 3·84 feet per day. At the Modane end, that is the French one, it averaged 3·80 feet per day. In 1864 at the Italian end, it averaged 5·58 feet per day, and in the same year 1864 at the French end, it averaged 4·19 feet per day. In the year 1865 it averaged 6·88 feet per day at the Italian end, and 4·11 feet at the French end.

796. (*Col. Harness.*) Are those days 24 hours?—Yes; they work night and day.

797. (*Chairman.*) Then what you call a day in that table means 24 hours?—Yes; they never stop in the tunnel; they work night and day. I shall also read an extract from a report of Captain Tyler to the Board of Trade on the subject of the proposed railway over Mont Cenis, in which he treats of the rate of progress which has been maintained in the construction of this tunnel. This report is dated the 12th of June 1865, and in page No. 1, he states, "I took the "opportunity of visiting this tunnel. I found that "headings had been driven for 2,011 metres from "Modane, and 2,700 metres from Bardonnéche, "leaving 7,509 metres (about 4⅔ English miles) to be "yet pierced." In page No. 2, he states, "Looking to "the state of progress which has hitherto been effected, "and the probable nature of the rocks, it cannot be "expected, without taking into account any extra "difficulties of ventilation, or from water which may "be encountered, that this tunnel can be completed "in less than from seven to eight years." Upon that I may make this note, that taking the time as eight years, this would give a daily average of about 4 feet 3 inches at each end or working face, and that was for the central or the most difficult part of the tunnel where they were two miles from either end. In the construction of the Kirkstone Pass tunnel, we have estimated the rate of progress at 4 feet per day at each face.

The witness delivered in the following statement:

TABLE showing the Progress of MONT CENIS Tunnel effected by the boring machinery there, during the years 1863, 1864, and 1865.

At the Bardonnéche end (Italy).	Metres.	Feet.	Feet per day.
1863	426	1,398	3·84
1864	621	2,037	5·58
1865	765	2,510	6·88

At the Modane end (France).	Metres.	Feet.	Feet per day.
1863	367	1,204	3·80
1864	467	1,532	4·19
1865	458	1,508	4·11

R. Hassard, Esq.

20 Feb. 1867.

798. Are you aware whether the works on Mont Cenis tunnel have gone on with the same degree of speed at both ends?—At the Bardonnéche end the works have gone on with a greater degree of speed; at the Modane end they have been working for nine months through some hard quartz, and in that case they have averaged, I think, 2·80 feet per day, but that quartz they anticipate that they are nearly through now. But a great increase has taken place at the Bardonnéche end, greater than I have put in that table.

799. Since that report of Captain Tyler's, the rate per day having been exceeded at one end and having diminished at the other end, what would that bring the average down to?—It still leaves a greater average than 4 feet.

800. You have described the mode of construction of your aqueduct up to Stockport; will you proceed now to describe the construction for the remainder of the way?—Through the midland counties where we get to a great extent out of the rock formation that we pass through the whole distance from Ullswater to near Manchester, at all events when we get beyond the Potteries, we should get into the clay districts of Leicestershire and Northamptonshire, and for that portion of the work where it is much lighter, a rather different mode of construction would be adopted, something in the manner shown in this section (*producing the same*). We should use Portland cement concrete to a great extent, which forms an imperishable material, and line the aqueduct with bricks, putting the upper portion, where it might be exposed by the variation of the level of the water, of Staffordshire bricks. That section shows one mode of construction and the other side shows the conduit with a rendering or a coating of Portland cement, which is found to be a most durable material. They are constructing now a sewer in London wholly of Portland cement concrete, and using no brick at all; I refer to the sewer at Bridge road, Battersea. This section shows a piece of covered way constructed of Portland cement concrete protected with brick; the bottom is covered with a Portland cement rendering, and the arching is of brick in the ordinary way. If we met with rubble we should use it, backed with concrete, for the sides and bottom, something in the same way as rubble is proposed to be used in the northern portion. The one section shows a fall of not quite 5 inches per mile, it being 28 feet in width at the water line. The other section is for a fall of 6 inches per mile and 26 feet in width at the water line. Some fear was expressed as to the raised aqueduct. I have drawn an alternative one which can be made at the same expense. It is proposed to be made on iron ribs with cast-iron plates between, such as Mr. Harrison is aware are used for tanks at railway stations. Those ribs are 4 feet apart and they are tied across at the top with a piece of rolled girder, which effectually supports the structure and affords the means of carrying a foot-path along it.

801. (*Mr. Harrison.*) It is merely a question of price I presume?—This plan is just about the same rate of price as the one I showed you before.

802. (*Chairman.*) Is what you have just described the mode in which you propose to carry the water through the midland districts?—Yes.

803. That is the method you adopt from Stockport till you get to where?—To the reservoirs near London. There might be some short bits of tunnelling on the route and they would be constructed with brick in the ordinary method.

804. (*Sir B. Phillips.*) You spoke, did you not, of coating this aqueduct with cement?—We should either face the concrete with brick or render it with cement.

805. Would there be no fear of corrosion eventually to the lining of the aqueduct from the action of the water?—Not the slightest. Portland cement is perfectly imperishable when it is of good quality.

806. (*Mr. Harrison.*) Of course, that is the important question, that is the great difficulty which all those who have to use it, I think, must admit?—The weight and the colour are sure tests. We find no difficulty at Barking in the construction of the metropolitan sewage works, inasmuch as from the weight and the colour we have the means of detecting at once any inferior quality.

807. (*Chairman.*) You consider, do you not, this part of the country which your aqueduct will traverse to London comparatively easy?—Compared with the other part, very easy indeed.

808. (*Mr. Harrison.*) Have you prepared any approximate section of it?—Not of that portion, but I have the Ordnance maps here with such an immense number of levels upon them that as to leave the selection of the route a matter of no difficulty, and they also enable us to make a very fair estimate of the probable amount of the work. The whole aqueduct from Ullswater to London averages 37,000*l.* per mile as against 38,000*l.* at which Mr. Bateman estimated his aqueduct. There is no very great difference between the two as to cost, Mr. Bateman's is a little more expensive in construction, he has contemplated using a much larger amount of brick, judging from the drawings which he exhibited here, whereas where we pass through a rocky country we use the rubble of the country.

809. But taking the simple assumption that in both cases you adopt the same form of conduit or the same form of aqueduct, he having at his power a larger fall per mile than you have, his works would be less than yours throughout, would they not; not in the direct ratio of the fall, but in something, perhaps, approximating to the square root of the fall?—Possibly that may be so, but I should be afraid to work with a greater velocity.

810. You mean in a lined conduit all through?—Yes; the aqueduct for either of these projects should be a work for all time, and any stoppage for repairs or anything of that kind would be a very serious matter. If I had a greater fall I should use it in the syphons, and I should put a smaller capacity of pipe with a greater fall; but I should be afraid to work with a greater fall in the conduits and tunnels in the ordinary portions of covered and uncovered aqueduct.

811. I should differ from you; but taking it irrespective of that question, there can be no doubt that the position which I put to you is perfectly correct?—Quite so.

812. Do you think that in a matter of such vast importance as a work embracing 12,000,000*l.* of capital you, as an engineer, would be prepared to advise any parties to undertake such a work upon an approximate estimate, without actual sections of the country being taken?—Yes; I think that I have quite sufficient information to warrant me in making the assumption that the estimate is sufficient.

813. Within what per centage of the probable cost do you think you could fairly assume that you could arrive?—I believe that it could be done, and I believe that the estimate which I have given would not be exceeded. I know that it would not for the most northerly and most difficult portion of the work, because there we had the advantage of sections, and the thing has been gone into very carefully. I believe that the price which we have allowed for the remainder of the work would be ample to cover it, and would not be exceeded.

814. Without knowing how many miles of that work would be by piping, or how many miles would be by aqueduct, or what the extent of those aqueducts would be, you think that you could still arrive at a justifiable calculation?—I think so. Both projects are open to the same objection, but there would not be more than 10 miles of iron pipes, and that would be at the crossing of the Trent, and of that I have satisfied myself.

815. Approximately you could have prepared, could you not, a section so as to have sufficient heights throughout the whole of that distance, or you could have prepared a section in continuation of your

existing one ?—I will show you the information which I have got, and you shall judge for yourself.

816. Have you put that information in the form of sections ?—No, I have not.

817. What would be the probable cost of taking such sections as would enable you to complete your sections from end to end ?—That, of course, would be a matter of considerable cost for any private individual to incur, because if that were to be done, I think that it ought to be done well, and it would require a great deal of contouring and close examination of the country, but if such a scheme as this were determined to be carried out it might be done without any additional expense by the Ordnance authorities doing it ; they have levels all through the district, and it could be done by them as part of the national survey at a comparatively very small cost, but it would be a very heavy undertaking for any private individual to incur.

818 (*Chairman.*) How do you propose to construct the reservoir near London, and at what place do you propose to put it ?—About a mile north of Edgware is the place where we propose to construct the service reservoirs ; we should have them in duplicate, so that one might be cleansed while the other was in use.

819. What would be the size of each part of the reservoir ?—We have estimated them to contain 15 days supply at 250,000,000 gallons per day.

820. Do you intend that the 250,000,000 gallons should be contained in the whole reservoir or in each part ?—The 12 days supply at 250,000,000 gallons per day would be contained jointly in the two compartments of the regulating reservoir, and that would at an altitude of 220 feet above high-water, and 232 feet 6 inches above the Ordnance datum.

821. (*Sir B. Phillips.*) Do you think that a reservoir containing a supply for 15 days only would be sufficient ?—I think that it might be enlarged afterwards, at any future time additional reservoirs might be constructed if it was found not to be sufficient, but I apprehend that it would be sufficient.

822. Would it be safe with a population of 3,000,000 people to leave a supply of only 15 days, subject to any casualty that might happen ?—The reservoir might be made to any extent that was thought necessary.

823. What is the length, from point to point, of the line of aqueduct that you propose from Ullswater to London ?—From Ullswater to the reservoir is 270 miles.

824. (*Chairman.*) Will you describe the mode of construction of this reservoir at Edgware ?—It is intended to be constructed in the ordinary way, with sloped sides faced with stone or concrete.

825. (*Mr. Prestwich.*) Will you proceed with your description of the geological formation of the district through which the aqueduct is to pass, and first of all in the district through which you pass from the lakes to Manchester, do you pass through any coal formations ?—We pass for some distance over the coal measures, but for a very short distance over a locality where there have been any coal works. For four miles we pass over a locality where there have been a few coal workings, I believe that they are now abandoned, but I do not attach the slightest importance to the subject of coal measures. On those coal measures are situated all the reservoirs and waterworks, of those towns for the supply of which Mr. Bateman stated to the Commissioners the other day that no additional water is needed. On those coal measures are situated the great reservoirs supplying Liverpool, the great reservoirs of Rivington and Anglezark. The line of pipes conveying water to Liverpool is laid for a distance of probably 20 miles over those measures. The towns on those coal measures that have their own waterworks, as Mr. Bateman stated, are Blackburn, Over Darwen, Haslingden, Accrington, Heywood, Bury, Burnley, Middleton, Bolton, Oldham, and Rochdale ; they are all situated on the coal measures, and have their works of water supply existing on them, and in addition the whole country is studded over with reservoirs for canals and for mill purposes ; it is covered with towns, with manufactories, with dye works, chemical works, and with cotton mills, and it is intersected by canals, rivers, and railways, and no inconvenience is found to exist ; but over that four miles where there have been some coal workings we propose to lay four pipes, we will say, instead of three, laying them between the tanks at each end of those four miles, and some considerable distance apart, in fact, having a spare pipe, so that if accident happened to any one of the pipes the valves upon it would close, and the supply would be carried on through the remaining three. This map which I produce shows the line of aqueduct passing over a portion of that district on which, as I have mentioned, are situated the great reservoirs supplying Liverpool. You will also observe the Belmont reservoir, the works supplying Bolton, and other reservoirs and millponds all over it, and on the next sheet also you will find that there are a great number. On those four miles we propose to lay the pipes at some distance apart and, in fact, to lay an additional pipe. You may see how this country is covered with reservoirs. The portion near Bolton is covered with reservoirs, with mills, and with millponds, intersected with canals, with rivers, and with railways ; and the waterworks of all those towns are situated on those coal measures, and, as I have said, no difficulty is found to exist. But we propose to guard against accident, by having, in point of fact, for that four miles works as it were in duplicate, about a couple of hundred yards probably between each line of pipe.

826. If any slight subsidence occurs in a canal, it is easy to raise the level, but with pipes it is very different ?—In the case of an open canal, if fracture takes place in the bed owing to any subterranean working or anything of that kind it might drown the mine or working, because there could be no means of shutting off the water in the aqueduct ; but in the case of pipes, we should place what are called momentum gates or valves at each end, and if any fracture took place, the valves at each end of the fractured pipe would close, and the escape of water would be limited to whatever was in that section of the pipe.

827. You are probably aware that although you may only pass over four miles of actual coal workings, still, as it has been proposed to carry your aqueduct over the permean and the new red sandstone, it is possible that coal may exist under those formations which may be worked ?—No doubt it is so ; and in the portion of the aqueduct just north of Rivington, where there has been no coal working, and where, I believe, it was attempted once or twice and abandoned from being found not worth working, it would be very easy to buy a stripe of land on either side of the aqueduct so as to prevent its being underminded underneath, and that land could be let for agricultural purposes and so pay the interest upon its purchase.

828. The district to which the last question which I put to you had reference was the permean and the new red sandstone district of Cheshire ; is it not possible that coal may exist under those formations ?—I can only say that there are no coal workings there now ; of course, it is not easy to say where coal may or may not be found.

829. And if it were, you would anticipate no difficulty on that score ?—No difficulty whatever, and the remainder of the aqueduct avoids all the known coal fields.

830. You pass close by the Staffordshire coalfield, do you not ?—Our aqueduct passes round the south-western portion of the Staffordshire coalfield, from that it passes on along the table land of Needwood forest, crosses the river Trent about five miles south-west of Burton ; that is where the 10 miles of pipes probably would be. It then passes along the table land of Charnwood forest till it gets into the country traversed by the Ashby-de-la-Zouch canal, which is 53 miles in one level reach, and will give some idea of the easy nature of the country there.

R. Hassard, Esq.

20 Feb. 1867.

831. (*Mr. Harrison.*) What is the level above the Ordnance datum of the canal there?—315 feet; we should be something greater than that, about 330 feet; but the ground is all gently sloping and we can get any elevation we please.

832. (*Mr. Prestwich.*) For what distance do you pass over the permean and new red sandstone?—About 30 miles in the Cheshire district, and there are about 65 miles of the new red marls in addition,

833. Then you pass, do you not, over the oolites?—Then we get into the lias shales and limestone; then we get into the oolites and shales: then into the Oxford clay; then into the galt clay; then into the chalk, and lastly into the London clay.

834. Do you pass over the chalk area without tunnels?—No; there would be a tunnel common to both projects passing through the chalk, north of Watford.

835. Could not that tunnel be avoided by following the line of the canal; you are aware probably, of the great difficulty that was experienced in making that Watford tunnel, from the occurrence of sand pipes?—I know the engineer of that tunnel, and we had some discussion the other day on that subject, and from what he said I did not gather that that was his experience.

836. I visited that tunnel whilst it was in course of construction, and I remember that a very serious accident happened and a great deal of difficulty was experienced from the surface of the chalk being deeply indented with pipes of sand and gravel which they came upon unexpectedly and which gave way, in fact, there were pot-holes of gravel?—We should be deeper in the chalk than that, and the probability is that we should not meet with those.

837. (*Mr. Harrison.*) Is Shiffnal near Mr. Bateman's aqueduct?—Mr. Bateman's aqueduct passes some distance south of it.

838. Do you go close to Stoke?—We pass just outside the Staffordshire coalfield.

839. (*Chairman.*) At what do you estimate the cost of making the reservoir in London?—500,000*l.*

840. (*Sir J. Thwaites.*) That you can calculate, I presume, with something like certainty?—I did not take it out in very great detail; I calculated it according to the cubical contents.

841. How do you line it?—With concrete, and face the upper portion of it probably with brick, the lower portion we should line with Portland cement.

842. What depth of concrete would you use?—That would depend upon the material behind. Where it is London clay, an average of 18 inches would be sufficient; it might be a little less at the top and a little more at the bottom.

843. (*Mr. Prestwich.*) Does not Mr. Bateman provide for a three weeks supply?—No, I think not. I think it is only 15 days.

844. Are you not mistaken in that, he mentioned 21 days, did he not?—I do not recollect, but we have the same amount allowed for that reservoir, so that if Mr. Bateman could make it to contain 21 days supply for that money, we could do it. I have estimated it at a higher cost than Mr. Bateman.

845. (*Sir J. Thwaites.*) Then the cost of your scheme terminates at that reservoir?—The project may be said to terminate there, but we estimate for an aqueduct into London; the connections with the present works of the companies we have not included, and I think that Mr. Bateman has not done so either.

846. (*Chairman.*) Can you state to the Commissioners the total cost of your scheme from the lakes until you bring the water to the reservoir at Edgware?—Until we bring it into London, it is 13,500,000*l.* for a daily supply of 250,000,000 gallons.

847. Does that include everything?—Yes, everything.

848. That being the cost of bringing that quantity of water 270 miles?—280 miles altogether to London. The total cost of works, including contingencies, is 11,679,260*l.*, and to that we have added 1,820,740*l.* for interest on borrowed money during the construction of the works, being an average of something about two and a half years, and for other expenses which, of course, are contingent upon carrying out great works of this nature; we calculate an average of two and a half years, that is, supposing that the works take five years in construction.

849. (*Sir B. Phillips.*) During the progress of the works you charge 1,820,740*l.* for interest upon the principal?—Yes, to cover the interest upon borrowed money and professional and other expenses.

850. (*Chairman.*) With your experience of other works do you think that these works could be completed within five years from the scheme being sanctioned?—I have no doubt in the world that they could. The tunnel at Kirkstone Pass is the key of the whole, and with the same means and appliances that have been used at Mont Cenis, the tunnel, including the shafts and everything of that kind, could be carried through or completed in four years, or in four years and three months at the outside.

851. Would the 13,500,000*l.* include the purchase of land and compensation?—Yes, everything, land, compensation, easement, severance, and every other expense.

852. You object, do you not, to the scheme which has been propounded by Mr. Bateman?—I have some objections to offer to the Commissioners, but before I do so, I may probably as well hand in a list of the towns with their populations to which supplies could be given from our proposed aqueduct *in transitu*, either in aid of their existing supplies or wholly, if they choose to take it.

The witness delivered in the following table:

LAKE PROJECT.

Towns.	Population in 1861.	Towns.	Population in 1861.
BY GRAVITATION.		BY PUMPING.	
Kendal	12,029	Clithero	10,864
Lancaster	16,005	Burnley	28,700
Fleetwood	3,834	Haslingden	6,929
Preston	82,985	Blackburn	63,126
Ormskirk	6,426	Heywood	12,824
Wigan	37,658	Rochdale	38,184
St. Helens	18,396	Bolton	70,395
Liverpool and suburbs	600,000	Bury	37,653
		Middleton	9,876
Manchester and adjacent places	600,000	Oldham	94,344
		Macclesfield	36,101
Stafford	12,532	Congleton	12,344
Burton-on-Trent	13,761	The towns and the districts of the potteries	188,083
Tamworth	10,192		
		Lichfield	6,893
		Birmingham and the towns adjacent	573,036
		Hinckley	3,644
		Nuneaton	4,645
		Coventry	41,647
		Rugby	7,818
		Daventry	4,124
		Towcaster	2,715
		Leighton Buzzard	4,330
		Aylesbury	6,168
		Berkhampstead	3,631
		Hemel Hempstead	2,974
		Watford	4,385
Total by gravitation	1,413,818	Total by pumping	1,275,433
		Do. by gravitation	1,413,818
		Total	2,689,251

853. In one item in this table you put Birmingham and the towns adjacent; will you explain what you mean by the towns adjacent?—There are a number of towns in that country, for instance, Walsall, Dudley, Wednesbury, and other towns in the manufacturing district. I put it in that form merely to avoid lengthening the list.

854. I understand you to say that some of those towns may receive their supply by gravitation or by

pumping, either wholly or in part, from the new works Supposing them to want it wholly from the new works, what amount of water are you prepared to give to those towns, a list of which you have handed in?—It is not likely that they would take it wholly, but the capabilities of this project are 350,000,000 gallons per diem, that is to say, 250,000,000 gallons daily for London at a cost of 13,500,000*l.*, and an additional 100,000,000 gallons can be got from Bala and from the district immediately to the north of Windermere and Kendal.

855. We had better deal first of all with the present scheme exclusive of Bala. I understand you to say that this scheme which you have given us now at a cost of 13,500,000 of money, which is to include everything, proposes to give to London a supply of 250,000,000 gallons, leaving 100,000,000 gallons to be dealt with in another manner; would not that be so if you took 250,000,000 gallons for London?—The 13,500,000*l.* is for the supply of 250,000,000 gallons only.

856. Then in the event of your wishing to supply any or all of those towns either in part or wholly, the sum of 13,500,000*l.* would not enable you so to supply those towns?—If the consumption of London increased and came up to 250,000,000 gallons daily we should then have none to spare for other towns, and we should be obliged then to go to additional expense in order to get an additional supply.

857. Then in practice it comes to this, does it not, that if 250,000,000 gallons is required for London you have nothing wherewith to supply any other towns on the road?—Not without incurring additional outlay.

858. And you cannot get the 250,000,000 gallons except you spend 13,500,000*l.*?—Precisely so.

859. How do you propose to give the towns stated in this list a supply of water, either wholly or in part, is it by a supplemental and a different scheme?—In the first place, after the construction of these works, I do not think that the supply of London would jump up all of a sudden from its present amount to 250,000,000 gallons.

860. Could you state to us now what is the amount of the present supply to London?—The present supply to London is about 100,000,000 gallons daily, 108,000,000 gallons I think is the maximum which has been obtained, and I believe, judging from what one sees in public prints, that an additional quantity of about 42,000,000 per day is deemed requisite for the proper dilution of the sewage and the efficient working of the sewers.

861. (*Sir J. Thwaites.*) Are you not under some misapprehension upon that question?—I am only speaking from what I have seen in the public prints.

862. You have made the statement that so many million gallons may be required for the purposes of sewage, that is not so; it is simply a question of ventilating the sewers, and how to get rid of the gases which are generated in the sewers, and if the system of flushing the sewers were adopted it would require such and such a quantity of water, but that is merely speculative; there is no intention whatever of carrying such an arrangement out?—I am only speaking of what I have read.

863. (*Sir B. Phillips.*) If I understand you rightly, your works are constructed to deliver 250,000,000 per day to London, and your present estimate is that about 150,000,000 gallons is all that would be required for some considerable time?—No. The amount of water consumed in London is increasing so rapidly that I believe 150,000,000 gallons would, in a comparatively short space of time, be an insufficient supply for London.

864. How much do you suppose would be sufficient?—Not less than 50 gallons for each individual of the population. In the year 1850 the population of London was about 2,000,000, and the consumption of water was about 44,000,000 gallons per day. In 1856 it had increased to 81,000,000 gallons. In 1865 it amounted to 108,000,000 gallons, being an increase for the whole period of about 4,000,000 gallons daily per annum, and for the latter period about 3,000,000 gallons daily per annum, the individual consumption being then about 36 gallons per day. In 1850 the individual consumption was 22 gallons per day, and in 1865 it had increased to 36 gallons per day.

865. You propose to increase the supply from 36 gallons per head to 50 gallons?—I believe that a less quantity than 50 gallons per individual in a city like London would not be a safe estimate to reckon upon. It is actually now 36 gallons, and then in addition to the increased quantity of water per individual we have to deal with the extraordinary increase of population. In 1850 the population of London was 2,000,000, in 1865 it had increased to 3,000,000, and should it increase in the same ratio for 26 years we shall then have a population of about 5,000,000 of souls requiring a daily supply of 250,000,000 gallons. I take 26 years, because I estimate that the works might and would take probably six years from the time the project received the sanction of the Legislature, and then we should be providing with those 250,000,000 per day for a future not more than 20 years distant.

866. You are dealing now with 250,000,000 gallons for a population of 5,000,000 people, but the question which we want to arrive at in another form is as to what quantity is immediately required, and what the surplus between the quantity required in London and the quantity which you propose to deliver, would be, plus that delivered to those various towns?—I apprehend that for some time after those works were constructed the demand would not amount to 250,000,000 gallons, and that the residue which remained between the consumption of London and the capability of the works might be sold to intervening towns.

867. (*Chairman.*) You stated, did you not, that the maximum supply at present is, 108,000,000 gallons per diem?—Yes, that is 36 gallons per individual.

868. How much additional do you suppose is likely to be required in the space of the next 10 years?—The quantity of water consumed has increased from the year 1850 to the year 1865 at the average rate of about 4,000,000 gallons daily per annum.

869. (*Mr. Prestwich.*) Would it not be better to go back to the year 1830, because from 1850 to 1865 we have been told was an exceptional period, that large works were constructed for the existing waterworks which enabled them to supply that quantity, that is to say, that during those years the supply increased in a more rapid ratio than usual?—I cannot give the statistics from an earlier date than the year 1850, but it is not very easy to put a limit to the consumption of water when it is introduced among a large population, and to give an example of that, between the years of 1850 and 1856 the water supply nearly doubled in quantity.

870. Therefore, that hardly gives the exact ratio of increase?—No, and, therefore, I have taken it over a longer period of time, viz. from 1850 to 1865. The increase in the first six years of that period was at the rate of about 6,000,000 gallons per day, and in the latter period at the rate of 3,000,000 gallons per day. Where water has been introduced into other large towns, for instance, Manchester and Glasgow, it is scarcely possible to put a limit to its consumption when it can be sold at any moderate rate of price.

871. (*Sir B. Phillips.*) Are you aware Mr. Bateman told us that at Manchester they only consume 21 gallons per head per diem?—I do not know what they consume per individual, but I know they consume an enormous amount of water for trade and manufacturing purposes in Manchester. The amount of the public rate levied for water is 16,000*l.* a year, and of the domestic rate 23,000*l.*, the two rates amounting in the aggregate to 39,000*l.* per annum, whilst the amount of revenue derived from water sold for manufacturing purposes is 56,000*l.* a year, so that although they may consume only 21 gallons indivi-

R. Hassard, Esq.

20 Feb. 1867.

dually still there is an enormous quantity consumed for other purposes, for the trading and manufacturing purposes which are incident to any large population.

872. (*Colonel Harness.*) How is the water for manufacturing purposes paid for?—It is paid for at the rate of so much per thousand gallons; in Manchester it is sold for about 6*d.* per thousand gallons, in Glasgow it is sold for about 7*d.*

873. You say that so much is paid for domestic consumption and so much for manufacturing purposes; does the sum obtained from each of the two kinds of consumption give a fair measure of the quantities used in those two ways?—There are two rates levied in Manchester, a public rate and a domestic rate. The domestic rate is levied on house property only, and the public rate is on all property in return for the advantages which an unlimited water supply is supposed to give. The amount of the domestic rate in the year 1865 was 23,000*l.* and the amount of the public rate was 16,000*l.*, making a total of 39,000*l.*, and that was equivalent to a rate of 8*d.* in the pound on all the property in Manchester. There was a revenue derived from the sale of water for public and trading purposes of 56,000*l.*, which went to ease the public rates; the public and domestic rates, if not eased by the sale of water for public purposes, would have together amounted to 1*s.* 7*d.* instead of 8*d.*

874. Do you think that the supply of water for manufacturing purposes was in the same proportion to the supply for domestic and other public purposes as 56,000*l.* to 39,000*l.*?—I cannot tell the quantity used for public purposes there, but it evidently must be very large, because the price is about 6*d.* per thousand gallons, and the revenue is 56,000*l.*

875. (*Sir J. Thwaites.*) I understand that your estimate is 13,500,000*l.* for structural works and other incidental expenses for storing and conveying 250,000,000 gallons daily to the metropolis?—Yes.

876. But it is the case, is it not, that your storing capacity is limited to that quantity of 250,000,000 gallons?—No; the aqueduct is limited to deliver that quantity, but we could store much more.

877. Then your conveying capacity is limited to 250,000,000 gallons?—Yes.

878. Then I see by the list which you have handed in, that you have a population in the several towns of 2,689,251?—Yes.

879. Allowing 30 gallons per head, that would give 80,677,530 gallons per diem?—Yes.

880. Do you think that the supply which the population of London would require for the next 10 years would exceed 150,000,000 gallons?—Yes, I think it probably might at the end of 10 years. I should think that probably 175,000,000 or 180,000,000 would be nearer the mark.

881. Then for the next 10 years the capacity of your supply would be equal to the supply of the metropolis and the several towns enumerated in your list?—Yes.

882. It would be 260,000,000 gallons or rather over?—I think 50,000,000 gallons would go a long way towards the supply of those towns for a considerable period.

883. Then in the event of its being expedient that those several towns as well as the metropolis should be supplied from this source, you would have to give an increased capacity to your tunnels or construct other tunnels?—I shall show the way in which we would meet that. These red districts which you see upon this large map on the wall, you may also see upon the small one, and as the probability is that a great part of the consumption would be in those towns north of Liverpool and Manchester, it would be incumbent upon us either to construct this aqueduct of larger dimensions in the first instance than we have proposed it or to construct a fresh aqueduct for the conveyance of this water to those towns. When the London supply went beyond 250,000,000 gallons, I should prefer constructing a fresh aqueduct from this point (*pointing to the map*) for the supply of those towns.

884. I understood your answer to a question which I put to you, when you were under examination before, to be this, that so soon as the supply of the metropolis would have mastered the capacity of your storing power you would then seek for an auxiliary supply from the Bala lake?—Yes, from the Bala lake and from the red district on the map also. I should say that instead of taking it from the supplementary Westmorland district, in the first instance, immediately north of Kendal, we should take it from Bala, and we should introduce into the aqueduct at Stoke an equivalent quantity of water to that which had been sold on the route of the aqueduct between Ullswater and the potteries district.

885. Did I rightly understand your previous answer that all the water that would be abstracted from your tunnel up to the point of junction at Stoke would be compensated by a supply from the Bala lake?—We could supplement the quantity in our aqueduct from two districts, from the Bala lake and from the district north of Kendal, but we should take it first from the Bala lake.

886. Will you just give us the capacity of the gathering area coloured red?—It is 53 square miles, and that would yield between 70,000,000 and 80,000,000 gallons, based upon the same calculation as the supply from the adjacent district.

887. That red area in point of fact you think would yield a sufficient quantity of water to supply the several towns which you have enumerated in this list, allowing 30 gallons per head per diem?—Probably it would be quite sufficient.

888. But failing that supply, you could obtain a sufficient quantity from the Bala lake?—We could easily bring 50,000,000 or 60,000,000 gallons a day from Bala lake to our main conduit at the potteries and bring it on to London, or distribute such portion of it as might seem advisable in the Birmingham district, taking the residue to London.

889. In constituting that piece coloured red into a gathering ground with a fresh reservoir you would have to make an independent reservoir would you not, as there are no lakes to serve as reservoirs?—Precisely so. We should be dependent upon artificial reservoirs, the sites of which are indicated upon the larger map.

890. Have you formed any opinion as to the additional cost of doing that?—I think that bringing the water from the red district to a point as far south as Liverpool would cost 1,500,000*l.*

891. That 1,500,000*l.* is the cost of forming artificial reservoirs on the ground coloured red and an independent conduit as far as Manchester?—I take it to be the cost as far as the Liverpool reservoirs.

892. You gave us before, did you not, the cost of taking the additional supply from Bala lake?—It is 1,500,000*l.* also.

893. Is there any difference in the length?—Not very much.

894. You utilize the lake in that case?—Yes.

895. And heighten the surface level?—We propose to raise the water 5 feet and draw it off 7 feet below the present surface, which gives us the command of 12 feet, but it could not be raised more than 5 feet on account of the town of Bala and on account of the railway which is being constructed on the southern shore.

896. Having regard to the gathering ground coloured red and its yielding capacity, and also to the supply from the Bala lake, you are of opinion that an ample supply for the metropolis and the several towns enumerated could be obtained?—I have no doubt of it.

897. It is only a question of spending 3,000,000*l.* more?—Yes, 3,000,000*l.* more.

898. (*Mr. Prestwich.*) What would be the additional supply from Bala lake?—Between 50,000,000 and 60,000,000 gallons.

899. (*Sir B. Phillips.*) Going back to the supply of 250,000,000 gallons per day, did I rightly understand your answer to be that in your judgment at the end of 10 years something like 175,000,000 gallons per diem would be a sufficient quantity for the supply of London?—I think that the demand would attain that amount, but whether it would be a sufficient supply or not I am not prepared to say.

900. You have 75,000,000 gallons to deal with?—Yes.

901. Could that 75,000,000 per diem be sold after the rate of 10*l.* per 1,000,000 gallons, which I understand you to be the price to the intermediate towns?—I believe that a considerable portion of it could be sold. I have prepared a table of the rates which would be necessary to be levied in London supposing that no water was sold in the first instance to other towns, and also in the event of such sales taking place, which I beg leave to hand in to the Commission, and it is as follows:—

TABLE showing the relative POPULATION, VALUATIONS, RATES, and INDIVIDUAL CHARGES in Liverpool, Manchester, and Glasgow, as compared with those which would be necessary in London after the introduction of Water from the Lakes at a cost for new works of 13,500,000*l.*, supposing no Water sold in the first instance to other Towns, and afterwards in the event of such sales taking place.

Name of City.	Amount of the domestic rate.	Amount of the public rate.	Equivalent to a rate on all property of in the £.	Amount received from the sale of water for public and trading purposes.	Average annual charge for water per individual of the population.	Rate which would be necessary if not eased by the sale of water for public and trading purposes.	Average annual charge for water per individual, if not eased by the sale of water for public and trading purposes.	Amount of the valuation of house property.	Amount of the valuation of other than house property.	Total valuation.
	£	£	*s. d.*	£	*s. d.*	*s. d.*	*s. d.*	£	£	£
Liverpool, population 500,000 -	25,000	40,000	—	40,000	2 7	—	4 2	—	—	—
Manchester, population 600,000 -	23,000	16,000	0 8	56,000	1 4	1 7	3 2	600,000	600,000	1,200,000
Glasgow, population 400,000 -	48,000	7,000	1 1	35,000	2 9	1 6	4 6	600,000	600,000	1,200,000
London in 10 years, population, say 3,750,000.	833,333	—	0 10	250,000	4 5	1 1	5 1	15,000,000	5,000,000	20,000,000
London, if 25,000,000 gallons of water were sold daily to other towns at 10*l.* per million gallons.	742,083	—	0 9	250,000	4 0	1 1	5 1	15,000,000	5,000,000	20,000,000
London, if 50,000,000 gallons were so sold.	650,833	—	0 8	250,000	3 6	1 1	5 1	15,000,000	5,000,000	20,000,000

I take it that in 10 years from this time the population of London will amount to 3,750,000 people, and that the rateable value will amount to 20,000,000*l.* It is now between 15,000,000*l.* and 16,000,000*l.*, nearly 16,000,000*l.*, and it has increased during the last seven or eight years at the rate of 400,000*l.* per annum, which would make it at the same rate of increase 20,000,000*l.* at the expiration of 10 years. I estimate that no water is sold to the intervening towns in the first instance, but that a revenue of 250,000*l.* per annum is obtained from the sale of water in London for manufacturing and trading purposes, which is less than at the rate which is obtained in Liverpool and Manchester, or Glasgow.

902. (*Sir J. Thwaites.*) Will you tell us the quantity which you propose to supply for this 250,000*l.* What does that 250,000*l.* represent in water?—It would be about 30,000,000 gallons per day. I estimate that the water for trading purposes would be sold at 6*d.* per 1,000 gallons, being about the same price as is charged in Glasgow, Manchester, and Liverpool. 10*l.* per 1,000,000 gallons is what the water would cost when brought to London, and what it could be sold for in bulk to other towns.

903. (*Chairman.*) Do I rightly understand you to say that you expect to receive 250,000*l.* by the sale of 30,000,000 gallons of water per diem for public and trading purposes?—Yes.

904. (*Sir J. Thwaites.*) That gives you 250,000*l.* a year; is that plus the cost of management, or is it the gross receipt, or have you made out a balance sheet showing what the structural cost of your works would be, the quantity of water that you would sell, the rate at which you would sell it, what the cost would be to distribute it, and what the profit would be to a company supposing it were a commercial company?—I have not estimated it in that way, but I have estimated the rate which it would be necessary to levy on all the property in London, supposing the capital borrowed at 4 per cent., that 425,000*l.* per annum is paid to the existing water companies, and that 100,000*l.* is taken as the expenses of management.

905. Is that 425,000*l.* for the use of their distributing power?—It is to continue their dividends, we absorbing all their works.

906. That is in point of fact utilizing the present net work of pipes and arrangements?—Yes and the reservoirs to the utmost extent.

907. Taking possession in fact of all their property?—Yes, and continuing their dividends, which dividends now amount to about 417,000*l.*

908. Do you propose that that should be a continuous dividend?—I have estimated for it as such.

909. You have made no calculation, have you, as to any mode of getting rid of this charge, spreading it over a series of years by adding to the annual payment; providing a sinking fund in fact?—No, I have not.

910. You are to get 250,000*l.* for the sale of 30,000,000 gallons per diem; how are you to pay the 425,000*l.* to the companies?—Out of the rates levied on property; it would require an average rate of 10*d.* in the pound on all property, on the valuation of 20,000,000*l.*; the annual expenses we estimate in this way, 425,000*l.* to the water companies, 100,000*l.* for collection and management, and 540,000*l.* per annum for the interest on 13,500,000*l.* at 4 per cent.

911. What does 10*d.* in the pound produce?—It produces 833,333*l.*

912. What are those various sums added together?—There is 425,000*l.* to the water companies, 100,000*l.* per annum for management, and 540,000*l.* for interest at 4 per cent. upon the capital; those amount to 1,065,000*l.* That rate of 10*d.* in the pound will produce 833,333*l.*, and that with the addition of 250,000*l.* for the sale of water for public and trading purposes, would produce a total revenue of 1,083,333*l.*, being something like 18,000*l.* in excess of the annual expenditure.

913. The amount that you receive for public and trading purposes is over and above, is it not, the rate of 10*d.* in the pound levied over the whole of the metropolis?—Yes, the 10*d.* rate would be necessary after giving credit for the 250,000*l.* received for the sale of water.

R. Hassard, Esq.

20 Feb. 1867.

914. The 10*d.* in the pound would be merely for domestic purposes; it would supply no manufacturing and no public wants of the metropolis in any way?—It would supply every want, except such wants as those of private trade or manufacture; it would supply water for all public purposes.

915. The supply to private trade and manufactures would not be included in the 10*d.*?—No; we estimate the revenue of 250,000*l.* to be derived from the sale of water for the purposes I have mentioned in addition to the 10*d.* rate. The 10*d.* rate includes the whole rate that would be levied; it includes what is generally called the domestic and the public rate, that is to say, there might be a rate of probably 2*d.* in the pound on all property, and a rate of 1*s.* in the pound on the house property, but I have not subdivided it; I have taken it as an average rate over the whole metropolitan area.

916. (*Chairman.*) The 250,000*l.* I presume is for private manufacturers?—Yes, precisely. The 10*d.* rate would cover all the water for domestic purposes, and also for what are called public purposes.

917. (*Sir J. Thwaites.*) You have calculated 30,000,000 gallons as the probable quantity that would be used for trading purposes, the remainder would, I presume, be for domestic purposes, the extinction of fires, and many other purposes of that kind?—For a variety of other purposes.

918. (*Sir B. Phillips.*) You have stated the amount which you deem sufficient to continue the dividends to the existing water companies, and also to pay interest at the rate of 4 per cent. upon the 13,500,000*l.* which you propose to borrow?—Yes.

919. Have you made any provision by which this 13,500,000*l.* is to be repaid?—No, the usual way is that the money for carrying out works of this nature is borrowed upon the security of the rates of the town or district which is proposed to be supplied, and it is levied in the shape of an annual rate. That is the way in which it is done in Liverpool, Manchester, Glasgow, Dublin, and most other large towns.

920. Have you any sinking fund wherewith to repay this amount?—We have not provided it.

921. (*Mr. Harrison.*) Do you know what is the present amount which is paid for water for manufacturing purposes in London?—I do not, beyond this, that it is sold at rates varying from 6*d.* to 10*d.* per 1,000 gallons. The quantity I cannot tell.

922. Can you tell what the gross revenue of all the water companies was in 1865?—I think it was between 700,000*l.* and 750,000*l.*

923. It was 738,000*l.*, and you assume that you would get about 250,000*l.*, or about one-third of the present rate for manufactories and the public?—Yes.

924. Do you think that, at the present moment, anything like one-third is paid for water for manufacturing purposes?—I am not aware. I know that the quality of the water now supplied to London is such as to be unfit for a very great number of manufacturing purposes.

925. You have taken 425,000*l.* as the amount to be paid in dividends, are you aware that in 1865 the amount was 440,000*l.*?—No, I am not.

926. And you do not know what it was in 1866?—No, I do not, but if their receipts are greater, no doubt there would be greater property to represent them.

927. Probably you are not aware that the actual amount of gross revenue was 738,000*l.*, and that the actual amount paid in dividends and interest in 1865 was 440,000*l.*?—I was not aware of the precise amount, I thought it was something like 417,000*l.* or 418,000*l.*

928. Is it not generally understood that in 1866 they have again been increasing their supply and the amount of their dividends?—I am not aware of that.

929. Assuming that to be so, that would, of course, *pro tanto*, alter that portion of your calculations?—Not very much I apprehend, because if their receipts were larger there would be a greater amount of property to represent the increase.

930. You would have to convert that amount into capital, and the 4 per cent., of course, would be upon the larger amount?—No doubt.

931. Then the expenses of management of the present water companies being 288,000*l.* in 1865, you calculate that on this scheme being carried out the expenses would be reduced to 100,000*l.*?—I believe that 100,000*l.* would cover them very amply; their main expenses now are filtration and pumping and the intermittent service, and a variety of expenses of that nature, which would all be done away with.

932. Mr. Bateman calculated that there would be a considerable amount of valuable property which would be realized?—Yes; Mr. Bateman took that into account, but we did not in making our estimate.

933. You merely took it generally that the present cost of 288,000*l.* would be reduced to 100,000*l.* by the new system?—Yes.

934. Can you at all give any detail of that, as to what is the cost of filtration and pumping?—No, I cannot, but I can tell you what is the cost of filtration. I have here extracts from the evidence which was given before the Committee upon the Metropolis Water Bill in 1851 and 1852. For the New River Company, represented by Mr. W. C. Mylne, the cost of filtration was given then as 0·43*d.* per 1,000 gallons; for the Southwark and Vauxhall Water Company represented by Mr. Quick, it was given as one-eighth of a penny per 1,000 gallons; for the Grand Junction Company, represented by the same gentleman, it was given in also as one-eighth of a penny; by Mr. Hawksley, it was given in generally that it varied from one-eighth of a penny to a half penny per 1,000 gallons. On this point I would beg to hand in the following table:—

TABLE showing the COST at which FILTRATION was variously estimated by Engineers of great experience, as extracted from their Evidence given before the Committee on the Metropolitan Water Bill of 1851–52.

Name of Water Company.	Authority.	Cost of Filtration.
New River - -	Mr. W. C. Mylne	·43*d.* per 1,000 gals.
Southwark and Vauxhall.	Mr. Joseph Quick	⅛*d.* ditto.
Grand Junction -	Ditto - -	⅛*d.* ditto.
—	Mr. Hawksley -	⅛*d.* to ½*d.* ditto.

935. You do not at all know what the cost of pumping would be?—I do not know what the cost of pumping actually is. The cost of pumping can be easily calculated, but Mr. Hemans tells me that it is generally estimated at from 80,000*l.* to 100,000*l.*

936. That would get rid of the odd 88,000*l.* in round numbers?—Yes.

937. Then it is easy to calculate what the filtration would cost, assuming that to be so, and putting aside the question of the property saved, what other expenses would there be saved?—There would be a considerable saving, of course, in the number of officers necessary. There would be a considerable saving, first of all in the concentration of management, and next there would be a considerable saving in the number of employés which are now necessitated by the intermittent service system. In collection, of course, there would be a very large amount of saving, because each company now collects for itself, and if it were all concentrated under one board or under one authority it could be done very much cheaper.

938. The whole of those items would be perfectly easily ascertained, would they not, through the companies themselves?—Yes, I should think that there would be no difficulty in ascertaining the amount, or at all events in ascertaining what it ought to be.

939. Your conviction is that 100,000*l.* per annum would be abundant to maintain all the new works which you are going to construct, the 270 miles of aqueduct, the whole of the works of distribution in London, all the expenses of management, all the cost of collection,

and everything in connexion with the scheme ?—I think that would suffice for all.

940. Is that based upon any approximate calculation, or is it an assumption ?—It was roughly gone into, but not more than roughly. The amount of repairs or upholding the works I put at a very light figure indeed, because we do not think that there would be any large annual outlay on that account, or scarcely any.

940*a*. Seeing that between 1857 and 1865 the net amount divided or paid in dividends and interest has increased from 308,000*l*. to 440,000*l*. or more than 40 per cent. in a period of eight years, and that in all probability it would be eight years before the works could be completed, do you assume that in the meanwhile the water companies will stand where they are or that they will go on increasing their works ?—I understand that although of late years they have largely increased their outlay still their annual expenses have been also very largely increased, so that, in point of fact, their dividends remain where they were.

941. Their dividends may remain the same but have they not to pay an additional amount of interest on borrowed money ?—The 425,000*l*. that we have allowed for the dividends to the water companies includes the interest upon borrowed money.

942. I see by the return that while their expenses have increased from 224,000*l*. to 286,000*l*. or 62,000*l*. their net amount of dividend and interest has gone from 308,000*l*. to 440,000*l*., so that, of course, whether it be in dividend or in interest there is a very large and progressive increase in the amount which you would have to compensate them for ?—Yes, but then you would get a much larger amount of property than they possess at present.

943. In making any calculation in the commercial view of the question, would not the value of such property be a very important feature in the calculation ?—Yes, I think so, but I thought it safer to exclude it altogether. We did not know what it was and we did not wish to put anything in the estimate that might be considered problematical.

944. Did you take the same view as Mr. Bateman did, that any scheme of this sort could only be carried out on the assumption that by some Act of Parliament the whole of the water companies were bought up and placed under one control ?—I do not see that any scheme of this nature could be carried out otherwise. It is based upon the supposition that the ratepayers should be the proprietors of their own works and guardians of their own interests, if one may so express it.

945. You have mentioned the works at Aberdeen ; are you personally acquainted at all with the arrangements which are made for carrying out those works ?—I merely mentioned Aberdeen so far as the aqueduct is concerned, with relation to the velocity of the water in the aqueduct. I am not acquainted with the circumstances of Aberdeen.

946. (*Chairman.*) Those works at Aberdeen were I believe only opened last October, were they not ?—Yes, they were opened in the autumn of last year by the Queen.

947. (*Mr Harrison.*) To what extent on either side of your line of aqueduct do you assume that towns will be within reach of your water ?—Liverpool is a long way off, but we pass within a quarter of a mile of the pure water basins of their Rivington reservoirs, consequently we should only have to deliver the water into a pond a quarter of a mile distant from our aqueduct.

948. You take Manchester as one of the towns to be supplied, containing a population of 600,000 people, is not Manchester considered to be one of the towns that is best supplied with water in the kingdom ?—Yes, I believe that Manchester is very well supplied.

949. Perhaps you would hardly include Manchester in the list of your towns ?—Manchester, at present, I believe is extending its works, and it comes to a question whether a town should lay out capital in extending its waterworks or pay a rent for water from an aqueduct passing their doors.

950. In the case of Manchester, they are supplied by a continuous service, are they not ?—Yes.

951. Do you think it at all likely that you would be able to supply them profitably, they having all their works already constructed and water nearly as good as what you could supply them with ?—I do not think it likely that Manchester will take its supply from us, at all events for a long period to come ; but as the area of drainage from which the supply is derived, is comparatively limited, that period, in the event of our aqueduct being constructed, must, sooner or later, arrive.

952. Could Liverpool continue with its present supply, or would they be likely to require yours ?—I will state just what difference it would make to Liverpool. Liverpool has been contemplating of late incurring an outlay of 1,500,000*l*. in order to procure a daily supply of 20,000,000 gallons of water from Bala, of which, in all probability, for 20 years to come they would not be able to use more than 10,000,000 gallons, that is, in addition to their present supply, and the interest of 5 per cent. upon 1,500,000*l*. would be 75,000*l*. a year, and if you add 5,000*l*. a year to that for the cost of management, collection, superintendence, and repairs of permanent works, which is probably the least sum at which you could estimate it, it will amount to 80,000*l*. a year for the supply of 10,000,000 gallons per day. We, passing their works, could supply them with the same quantity of water at 35,000*l*. or 36,000*l*. a year, and we could then supply them with an additional 10,000,000 gallons in 20 years from this time, or at whatever time that supply was wanted. In other words, we could supply them with water at half the money at which they could get it from Bala.

953. Putting Liverpool out of the question, have you considered practically to what distance from your line of aqueduct it would be reasonable to suppose that you could supply towns, would it be within a distance of say 10 or 20 miles ?—I think that 10 miles is an easy and practicable distance.

954. You would probably not go beyond that distance ?—I think not, except in special cases.

955. Therefore you do not by your scheme supply any of those towns which lie on the east of your aqueduct — take Sheffield for instance ?—No, not at all.

956. You omit them altogether, you merely take a band of 10 miles on either side of the line, and take those towns which are practically on the line of your aqueduct ?—Precisely so. All those Yorkshire towns have been omitted, because we know that they can get from districts which are in their immediate vicinity a supply of very excellent water more cheaply than they could get it from the lakes, even if they combined for the purpose. We have therefore omitted them entirely.

957. In that particular district to which you refer as the means of supply for all those towns, is not the water of immense value to those towns for the purpose of manufacture ?—Water in that country is of extraordinary value, pure water especially, for dyeing, bleaching, and chemical operations, and works of that nature for which pure water is so especially valuable.

958. Have you given your attention at all to the question of the saving to the inhabitants of a town from the use of soft water as compared with hard water ?—I can only speak from the opinion of others, not from personal knowledge.

959. (*Sir John Thwaites.*) Do you know the reasons why the municipality of Paris have elected to use hard water instead of soft ?—No, I do not. I do not know whether they have soft water within a practicable distance.

960. They have two sources of supply, one of soft and the other of hard water, and they have elected the hard ?—I know that they have introduced chalk

R. Hassard, Esq.

20 Feb. 1867.

water for drinking purposes, but for what reason I am not aware.

961. (*Mr. Prestwich.*) They gave the preference to the water from a chalk district over the water from a granite and slate district?—I am not aware whether the expense of procuring the water would be the same in both cases.

962. The distance is rather greater for soft water, but not much, it being 140 miles in the one case and from 80 to 105 in the other.—I was not at all aware of the circumstances of the cases.

963. You are aware, are you not, that there is a great difference of opinion with regard to the use of soft and hard water for the purpose of drinking?—There is no difference of opinion in that respect in the north of England, or where soft water has been introduced in towns. Where it has not been introduced I have heard that there has been an opinion expressed against it, but where it has been introduced I never heard of a difference of opinion. I have never heard the superiority of soft water over hard water questioned where it has once been introduced.

964. (*Chairman.*) You consider, do you not, that Mr. Bateman's scheme is open to several objections?—Yes.

965. Is one of your objections to his scheme this, that the results of the rainfall in the district from whence he intends to take his water are not sufficiently known?—Yes, and that they are at variance with the returns of the gauges which have existed in the immediate localities for some period of time back.

966. But by that answer you do not mean that the observations actually taken at the gauges which were quoted by Mr. Bateman were incorrect?—Certainly not.

967. But that the returns from the gauges in the district which he has taken do not tally with the quantities registered from gauges in other parts of the district at no great distance?—That is not quite what I mean. I mean that the deductions which Mr. Bateman has arrived at from the result of gauges kept during the three wettest months of an exceptionally wet year, are not in accordance with the results of gauges in the immediate locality relative to the fall of three dry years.

968. Are you not aware that Mr. Bateman stated that it was not an unsually wet season in that particular district of the country?—Mr. Bateman stated that it was not, but Mr. Symons has informed me that it was a year 17 per cent. above the average, while it was 24 per cent. above the average in the lake district, that being a difference of only about 6 per cent.

969. Mr. Symons does not refer, does he, to that particular district which is alluded to by Mr. Bateman?—He referred to the adjoining locality; he had no returns of gauges except one in the immediate drainage area, but he had several from the localities around, and he informed me that although it was not quite so wet a year there as it had been in the lake district, still it was an exceptionally wet year.

970. (*Mr. Harrison.*) Mr. Symons is now going to look into that question. Have you, yourself, any returns from any of those gauges upon which you base your opinion of the actual rainfall?—Yes, I have. Immediately to the south of the drainage area of the southern portion of Mr. Bateman's scheme, and only four miles distant from it, at the town of Rhayader, there has been a rain gauge kept for the last five years It is situate at a considerable elevation, being at an altitude of 880 feet above the sea. It is also at a point which is peculiarly favourable for the deposition of rain, being open to a valley leading through the hills from the west and being also open to a valley leading through the hills from the south-west, and it is situated at the convergence of those two passes through the hills, and it is, I believe, as wet a place as there is to be found in that locality; and I am corroborated in that opinion by the returns of that gauge of Mr. Bateman's which he placed above Llanidloes on the same hill as the Rhayader gauge, but at a distance of probably six miles from it, and which gave more rain than any of tho other gauges. I will give the returns at the Rhayader gauge. In the year 1863 the rainfall was 42·72 inches; in the year 1864 it was 37·02 inches; and in the year 1865 it was 41·48 inches; being a mean rainfall for those three years of 40·31 inches. There is another gauge kept at Llanidloes which is within the Severn drainage area, but that has only been kept for a short time. In the year 1865 at that gauge, which is about 750 feet above the sea, the rainfall was 43·33 inches, or not much more than that indicated by the Rhayader gauge. So that judging from the returns of those gauges I am of opinion that a greater rainfall than 42 inches could not be reckoned upon in three successive dry years over that drainage area. And I am further corroborated in that opinion by having worked it out by analogy from the same gauges that Mr. Bateman gave in the lake district, and comparing the rainfall for those three months with the rainfall of the year 1865 in the same locality, and reasoning in the same way for the Welsh district, I get a mean rainfall of 41·62 inches.

971. (*Col. Harness.*) Is the Rhayader gauge to which you refer the same as that to which Mr. Symons referred, or a different one?—There is only one.

972. (*Chairman.*) At page 6 of Mr. Bateman's evidence of the 6th of February, in answer to question 23, he says, "At Rhayader which is at the head of "the river Wye, getting into rather more open "country, and which is 880 feet above the level of "the sea, the rainfall was 41½ inches; at Llanidloes, "which is 750 feet above the level of the sea, it was "43⅓ inches; the average of all those figures is 59¼ "inches. Now in order to draw conclusions from "those facts as compared with gauges which have "been kept in other parts of the country, I have taken "nine places as nearly as possible under similar cir-"cumstances, but giving the advantage in point of "altitude to the mountain gauges which have been "kept in the lake district"?—I take those very same nine gauges which he has emunerated and I get a very different result.

973. You differ from Mr. Bateman in the deductions which he draws from those figures?—Yes, entirely.

974. That is one part of the objection which you entertain to Mr. Bateman's scheme; that the information which he has obtained as to the rainfall is not reliable?—In my opinion it is not sufficiently extended to enable a safe deduction to be drawn from it.

975. (*Mr. Prestwich.*) In the only one which you have given us you appear to agree very much with Mr. Bateman?—I agree with him, but that I conceive is the wettest place in the whole locality. The gauge which Mr. Bateman placed between Rhayader and Llanidloes gave a higher return than any other gauge that he had used. You will find in Mr. Bateman's estimate of rain in the Welsh district he gives returns of two gauges, in the one case of 29·80, and in the other of 29·90 inches, that is, out of six gauges two of them represented a very high ratio of rain; that would be one-third of the number of gauges, but the elevated area which these two gauges represent is only about one-fifth of the whole drainage area, so that to take those in the arithmetical mean will not give you a true return. I make the true mean rainfall according to those gauges as 17·34 as against, I think, the arithmetical mean of 18·59 inches.

976. (*Mr. Prestwich.*) Then admitting the gaugings in Wales, so far as we know them, to be correct, upon what grounds do you draw a different conclusion from Mr. Bateman?—Mr. Bateman reasoned that from those returns, compared with similar returns in the lake district, you could reckon upon 48 inches of available rain during a succession of three dry years, and for the purposes of that reasoning he took the returns of these nine rain gauges in the lake district, Keswick, Scaw Fell Pike, Derwent Island, Great End, Brant Rigg, Esk Hause, High Close, Ambleside, Patterdale Hall, and Wastdale Head.

977. (*Chairman.*) Mr. Bateman is asked in page 9, at question 35, "Calculating that you have a

" plus of 48 inches, what will that area yield?—(*A.*) " In my calculations I have not assumed 48 inches, " I have no doubt that I should be justified in doing " so, but I have taken 36 inches." Then at question 36, he is asked, " I understand you to say that 48 inches " is what is available in the Glasgow district?—(*A.*) " Yes, and what would be available in the Welsh " district, because I believe that the rain would be " the same or almost the same, year by year. By " these calculations I think that we should be quite " safe in taking 48 inches as the net available produce " of the water in this district; but in my calculations " I have only taken 36 inches, and that is only three " inches more than we are actually collecting and " delivering in the Manchester waterworks, although " the average rain will probably be 40 or 50 per cent. " more in the Welsh district than it is in the Man- " chester district." You join issue with Mr. Bateman, upon the probable amount of water to be gathered in that district?—I do.

978. That is one objection which you have to his scheme?—It is.

979. Have you any fault to find with the drainage area, either as to its being enclosed or any other reason?—Yes; a great part of the drainage area, probably one half of the entire, is enclosed land, pretty thickly populated, and under cultivation and tillage, and to that cause may probably be attributed the comparatively large quantity of organic matter that those waters contain.

980. Before going into that you say that one half of the drainage area is under cultivation and tillage?—Probably one half.

981. What do you understand by the words " cultivation and tillage"?—Land that has been broken up or is in the course of being broken up, and cultivated; farm lands occupied by farm houses and used for farming purposes.

982. Would you call half the drainage area arable land?—Enclosed square fields with a great deal of arable land, all the valleys cultivated, and some of them highly cultivated.

983. Are we to understand you that half the drainage area is under the plough, or only occupied as farms?—Half of it is enclosed land, and a great deal of that half under the plough, and to that circumstance, I think, may be attributed the comparatively large quantity of organic matter which those waters contain. And I may prelude what I am going to say by stating that samples of water taken from rivers and streams in summer, when there is nothing but spring water flowing down, will not fairly represent the quality of the water which may be derived from the same district throughout other portions of the year. As we get on towards autumn and up to midwinter, when it is about its maximum, the quantity of organic matter increases largely in waters of that kind, and therefore a sample taken in the height of summer cannot be considered a fair sample of water. The increase of organic matter is due to the decaying vegetation of autumn. The presence of organic matter in water is always attributable to decomposing animal and vegetable matter, and it is about the most deleterious ingredient that water can contain; in fact, among chemists water which contains more than one grain of organic matter per imperial gallon is not considered a fit or proper water for domestic use, and waters which are similar in other respects will take their rank in the standard of excellence, in the inverse ratio of the quantity of organic matter that they respectively contain. And having said that I may possibly surprise your Grace and the other members of the Commission if I tell you that water from those Welsh streams when taken in summer actually contains nearly 50 per cent. of organic matter more than the water supplied to London by the water companies at the same period. If you will turn to page 15 of Mr. Bateman's pamphlet you will find the quantity of organic matter there given as being 1·35 grains per gallon. A gallon of water weighs 70,000 grains, and consequently that represents 1·35 parts in 70,000, and that is equivalent to 1·93 parts in 100,000 parts. I now hand in a copy of the Registrar General's Report, dated the 27th of August 1866, in which there is an analysis given of the condition of the waters supplied to London for the previous week. The analysis is by Professor Frankland, and the quantities of organic matter in the waters then supplied vary from 1·80 to 0·89 parts in 100,000 parts, giving a mean of 1·33 parts in 100,000 parts, as against 1·93 parts in 100,000 parts in the Welsh waters, being an increase of organic matter of 0·47 per cent., so that as far as organic matter is concerned the Welsh water contains a much larger proportion than the London water.

The witness delivered in the following table:

EXTRACT from the REGISTRAR GENERAL'S REPORT, dated August 27, 1866. The analysis of waters for the month of August being by Professor Frankland, F.R.S.

Companies.	Number of houses supplied in July 1866.	Average daily supply of water in gallons during the month of July 1866.	Solid matter in 100,000 parts of the waters.	Organic and other volatile matter included in column 4.	Amount of oxygen required for oxidation of organic matter.	Total Hardness.
THAMES:—						
Chelsea	26,463	8,671,600	24·89	1·29	·0344	17·4
West Middlesex	36,000	9,090,414	23·62	1·16	·0304	16·2
Southwark and Vauxhall	73,857	12,180,000	23·66	0·98	·0336	16·2
Grand Junction	25,636	9,800,484	25·00	1·09	·0368	16·8

South Essex	750	160,000	38·04	1·80	·0108	22·2
			Average	1·33		

984. (*Mr. Harrison.*) The table which you find in Mr. Bateman's evidence does not give 1·93?—1·93 is the proportion in 100,000 parts. He gives the number of grains per gallon at different points in detail, but at page 15 of his report, he says, the " average amount of organic impurity being 1·35 grains per gallon," and I have taken it that the average of the whole is the same as Mr. Bateman gives in his pamphlet, and 1·35 grains per gallon gives us 1·93 parts in 100,000 parts.

985. If you refer to the note to the table on page 13 of his evidence you will see that he excludes that which is the largest source as being an impure water but he includes it in this calculation here?—No, I

R. Hassard, Esq.

20 Feb. 1867.

fancy not, because it would give a very much larger return than 1·35 if that was included. I will now hand in another return of the Registrar General, dated 28th January of this year, in order to show that the organic matter increases considerably in streams and rivers up to mid-winter, when it is at its highest.

The witness delivered in the following table:

EXTRACT from the REGISTRAR GENERAL'S REPORT, dated January 28th, 1867. The analysis of waters for the month of January is by Professor Frankland, F.R.S.

Companies.	Number of houses supplied in Dec. 1866.	Average daily supply of water in gallons during the month of Dec. 1866.	Solid matter in 100,000 parts of the waters.	Organic and other volatile matter included in column 4.	Amount of oxygen required for oxidation of organic matter.	Total hardness.
THAMES:—						
Chelsea	26,783	7,786,200	31·34	2·39	·0532	18·5
West Middlesex	36,331	7,872,706	31·99	2·33	·0532	18·8

Grand Junction	26,450	8,650,150	32·82	1·28	·0597	19·4
Lambeth	37,165	8,819,100	31·88	2·32	·0597	19·4
OTHER SOURCES:—						
Kent	33,693	6,149,006	39·40	1·22	·0223	22·5
New River	112,852	21,621,000	31·39	0·69	·0432	19·4
East London	90,174	19,842,000	35·68	2·64	·0727	20·5
South Essex	910	183,497	37·93	3·02	·0140	22·2
			Average	2·05	Being 57 per cent. more than the quantity of organic matter contained in these waters in summer.	

986. (*Chairman.*) What particular stream does the Registrar General refer to in that report?—He refers to all the London waters. I now beg to hand in a table showing the comparative amounts of organic matter in waters from Wales, in the waters now supplied to London, and in waters from the Lakes.

TABLE showing the comparative Amount of Organic Matter in Water from the Severn District—in Waters supplied to London, in January 1867, by the Water Companies—and in Water from the Lakes, the Samples for Analysis having been taken in the Month of January.

Name.	Grains of organic matter in a gallon of water.	Equivalent quantity in 100,000 parts of the waters.	Equivalent quantity in 100,000 parts of the water when taken in winter.	Observations.
Severn waters	1·35	1·93	3·06	With ·57 per cent. added to the quantity in summer, to represent its condition in winter.
London waters	— In winter.	—	2·05	
Lake waters	·58	—	·83	Samples taken in winter.

Consequently, the Severn waters contain about $3\frac{3}{4}$ times, and the London waters about $2\frac{1}{2}$ times the quantity of organic matter present in the Lake waters.

987. Would not the streams in the mountainous districts of the country be subject to a great quantity of the same organic matter coming down in what would be called in the south country the height of of summer; perhaps not to so great a degree as in mid-winter, but very much more than would be the case in the southern part of the kingdom?—No, quite the contrary. In this drainage area, or in the mountainous district at least, only a portion of it is so subject. There is a great portion of the valleys under cultivation and tillage, and the amount of organic matter which comes down in autumn is greater, being then due to the decaying vegetation of the district. In the summer time the amount of organic matter is always less in rivers and streams than it is at any other period of the year.

988. What months do you consider summer months for this purpose?—Say the month of June or July.

989. Are you not aware that in the north of Scotland there are very often considerable floods in the month of May from the snow melting on the hills?—But that does not bring down organic matter; the organic matter is gone. There is scarcely any in such a district. It is bare rock and uncultivated ground; it brings down a quantity of matter in suspension no doubt but no organic matter.

990. When you speak of this district do you mean the Welsh district?—I mean generally a mountainous district.

991. Surely you would not call the Scotch hill district a district of bare rock, from which no organic matter could be brought down?—Very little organic matter comes from such a district; organic matter is due to decaying vegetation or decaying animal matter.

992. Would not streams, which pass over a great quantity of peat, be constantly carrying down organic matter?—Certainly not; that is quite a distinct question.

993. Then would you consider that in a stream which was as pure as crystal in the morning and was more like porter in the evening there would be no organic matter?—It might be quite free from organic matter.

994. (*Mr. Prestwich.*) A peaty solution surely would be organic matter, would it not?—No, it is not due to decomposition in such a case; it is not generally considered in the light in which organic matter is spoken of.

995. (*Chairman.*) Are not those great peat mosses made up from the decay of vegetable matter?—They are not vegetable matters in a state of decomposition; I wish to draw that distinction. They are vegetable matters, no doubt, but not in a state of decomposition.

996. Because they are decomposed?—Peat is an antiseptic; it is one of the strongest correctives of decomposition that we have.

997. It is rotted trees, is it not?—I have repeatedly seen trees which have been dug out of peat bogs, which

have been there for thousands of years, and which were as fresh as possible when dug out.

998. That particular tree might be fresh, but all the matter surrounding it would be in a state of decomposition?—It is not considered so with relation to water.

999. (*Sir J. Thwaites.*) I presume your notion of organic matter has rather reference to the decomposed vegetable matter, the result of manuring?—Precisely; the decomposed vegetable and animal matter.

1000. (*Mr. Prestwich.*) In analysing water you cannot distinguish, can you, whether the organic matter is derived from peat or from decomposing animal matter or vegetable matter?—In any analysis of water that I have seen there has always been some statement to that effect, separating if there is anything due to peat from what is due to decomposing organic matter.

1001. (*Chairman.*) Then I gather that your objection is that the analysis of the water has been made at a time of the year when a correct analysis could not be made?—Yes, and that the water in Mr. Bateman's scheme actually contains more organic matter than the water now supplied to London.

1002. And that the water so analysed, even at a favourable period of the year, as you say, contains more impurity than the water supplied to London at the same period?—Yes.

1003. (*Sir B. Phillips.*) You spoke just now of the increased impurity of water in midwinter, have you any return to show that?—In midwinter there has been no return given of the increase of organic matter in the Welsh waters, but I have handed in a second published return of the Registrar General, dated the 28th of January of this year, in which the mean of the organic matter in the water delivered in London is 2·05 parts in 100,000 parts as against 1·33 parts in the same water delivered in summer, which is an increase of 57 per cent. owing, I have no doubt, to the decaying vegetation of the autumn.

1004. Have you any return of the same period and from the other districts?—I have from our own district.

1005. I mean from the Welsh district?—For comparison with the Welsh district I have added to the Welsh water the same percentage of excess of organic matter which is present in the London waters in winter as compared with the same waters obtained in summer.

1006. That is an assumption, is it not?—Yes, it is an assumption, and in that way we find that in winter the Severn waters would contain 3·06 parts of organic matter in 100,000 parts; that is, with 57 per cent. added to the quantity in summer, being the same proportion in which organic matter in the London waters in winter exceeds the amount in summer. In the London waters it is as I have mentioned, 2·05 parts in 100,000 parts, and in the lake waters which were taken purposely in the month of January, as being the period in which we should naturally expect most organic matter, the quantity of organic matter amounted to ·58 parts of a grain in a gallon of water; that is equal to ·83 parts of organic matter in 100,000 parts, and from this it may fairly be assumed that the Severn water would contain about $3\frac{3}{4}$ times, and the London water about $2\frac{1}{2}$ times, the quantity of organic matter that is present in the lake water.

1007. (*Col. Harness.*) You are assuming, are you not, that Dr. Thomson's analysis was made of water taken in the summer?—It is so stated in Mr. Bateman's pamphlet.

1008. Do you not observe that Mr. Bateman, at page 13 of his evidence, has omitted the Severn water proper?—Yes, it must have been omitted and therefore the impurity comes out less, but there are some other streams which have been omitted which would quite make up the difference.

1009. His average is evidently taken from this table, including the Severn water proper?—But there are some other streams which are not included in that, which would fully make up the the difference I have mentioned.

1010. (*Mr. Prestwich.*) Would you not also consider that the conditions of such a river as the Thames are very different from the conditions of the Welsh streams?—Not in that respect.

1011. (*Chairman.*) What is the formation of the lower portion of the district from which Mr. Bateman gathers his water?—All the lower parts of the district and all the valleys are covered with a dense coating of clay, which is all cultivated. There are one or two exceptions certainly, but generally speaking, almost all the beds of the streams are formed in this dense clay, and a very small amount of rain is sufficient to render them perfectly turbid as I myself saw quite recently. If it is wished I can give the details of the condition of the water in several of these streams after a certain number of hours of rain.

1012. (*Mr. Prestwich.*) The clay of that district is accumulated principally in the valleys, is it not?—Yes, but some of the hills to a considerable height are covered with clay and cultivated, others are covered with clay, and cultivated over the very hill top, and both on the hill sides and in the valleys there is this dense clay.

1013. (*Sir J. Thwaites.*) I presume the cultivation is a question of degree in the higher parts?—Of course, higher up the hills it is mostly slight. The ground is broken up occasionally, but in the lower portions of the district, in the valleys, it is all more or less arable land, and there are some as good farm houses and as fine farmsteadings and buildings there as you will see anywhere in England.

1014. (*Chairman.*) What would be the size of those holdings?—They are fine large farms.

1015. My question had reference to the hilly district in Mr. Bateman's scheme?—The northern district near Llanwddyn is clean good ground, and therefore I wish to except that from the remarks which I now make. All the lower portion, the more southern portion of the district, for instance, near Canoffice, that district is all cultivated land; every one of those names which you see upon the map represents a farm house, or a cluster of houses.

1016. What is the size of those holdings?—I should say that they must be in the low ground probably 60 or 70 acres, or something of that nature.

1017. What would those holdings of about 60 acres represent in rent?—I did not inquire what the rent was, but the land is all very well cultivated, and they are a most excellent class of farmers, but what the rent is I cannot tell.

1018. What would you put it at per acre?—I should say for those farms probably the average rent would be from 1*l.* to 1*l.* 5*s.* an acre. The southern portion I should think would be much more valuable. The site of the Trefeglwys reservoir is covered with very fine farms indeed.

1019. Holding from 60 to 80 acres of land averaging 1*l.* an acre, do they farm very highly?—All the lower portion is very well cultivated.

1020. The land over the hills, I presume, is not broken up?—Over some of the hills in the lower portion it is tilled and enclosed to the very hill top, especially in the southern and eastern parts of the drainage areas.

1021. (*Sir J. Thwaites.*) You mean that they are pasturage?—They are pasturage and broken up, and relaid with artificial grasses. In the north-western portion, the Llanwddyn portion, there is a good deal of hilly ground, and therefore my remarks do not apply to that portion.

1022. (*Chairman.*) The ground would be broken up every two years?—I cannot say that, but it is repeatedly broken up. I may mention that I am just now told by the gentleman who was down with me that he made inquiries at Garthbibio and at Trefeglwys, and was informed that the rent at Garthbibio was 30*s.* an acre, and at Trefeglwys it was about 2*l.* an acre, but that was the best class of land.

1023. That would not range over a very large district, those would be exceptional prices, I presume?—Yes, in giving an estimate of the rent I gave 1*l.* to 1*l.* 5*s.* as the general rent.

R. Hassard, Esq.
20 Feb. 1867.

1024. I assume some sheep walks would not let for over 2*s.* 6*d.* an acre?—A considerable portion of the north-western part near Llanwddyn is sheep walks, and I presume that that land would average about 2*s.* 6*d.* an acre. There is peat in that locality. There are some extensive grouse shootings there. Lord Powis has some very large grouse shootings there.

1025. You say that the clay causes the streams to become turbid in a very short time?—Very turbid.

1026. Have you any objections of a particular nature connected with factories to the southern portion of this gathering ground?—There are two woollen factories in that district, above the points at which the water is proposed to be abstracted. There is one above Llanidloes and another in the district draining into the Tylwch river south of the Llanidloes, those are flannel manufactories.

1027. (*Sir J. Thwaites.*) There are no dyes used in that manufacture are there?—No; there is a great deal of wool washing, but I am not aware as to dyes. I should imagine not, as it is the native flannel.

1028. (*Chairman.*) Would a woollen manufactory, such as you describe, have any effect upon the water?—Wool-washing, which is largely carried on, is certainly not a matter which would improve the water. But there are only two woollen manufactories, and they are a small matter compared with a large area.

1029. In fact, you do not lay any stress on the woollen water?—No.

1030. (*Sir J. Thwaites.*) The water is used merely to wash out the oily matter, is it not?—Yes, I believe that is the process.

1031. (*Chairman.*) Do you consider that in this district it would be necessary to have those works connected with filtration?—Yes, undoubtedly; in the southern portion of the project it could not be avoided, in the northern portion it possibly might.

1032. Will you first explain why that could not be avoided in the southern portion?—In order to avoid filtration and to adopt the separating system, as is practised at Manchester, it is necessary to have two reservoirs, an upper and a lower one. When the water is turbid it is allowed to pass on into the lower reservoir, and it is there impounded for compensation, and when it is comparatively pure it is turned into the upper reservoir, and there stored for the town's supply; but you will perceive that in the southern portion of the scheme there is only one reservoir, because the smaller ones proposed on the Clywedog river and on the Tylwch river, the last-mentioned of which, however, could scarcely be made as a railway occupies the valley, are so small, compared with the large reservoir, that they would count for nothing, and therefore you will find that the water both for supply and compensation, and whether turbid or otherwise, must be stored in Trefeglwys reservoir, and that would render filtration absolutely indispensable in my judgment. The separation system could not there be practised.

1033. Do I rightly understand you to state that one place which was contemplated by Mr. Bateman for a reservoir is a place in which he could not put one?—Yes, the district south of Llanidloes, in which Mr. Bateman states, that the sites for the reservoirs have not yet been surveyed; reservoirs could not be made, because the valleys which are available for that purpose are now occupied by railways.

1034. Have you any idea how it is that Mr. Bateman proposes to put a reservoir in a place where he must know that he could not do it?—The railway may not have been opened, or Mr. Bateman may not have been aware of its existence at the time he surveyed this country. It is the Mid-Wales Railway, and it has been opened, I think, about 12 months.

1035. (*Mr. Harrison.*) The construction of that railway has been in operation for the last six or seven years, has it not?—I am not aware of that.

1036. (*Chairman.*) Would you not have thought that from Mr. Bateman's connexion with engineers he must have known of that?—All I can say is that there is no site available for the construction of a reservoir in that district, except valleys traversed by railways. The level of the rails is only a few feet above the water surface, and the river is crossed in several places by the railway. I have here a letter which I can put in if necessary, from the agent of the contractor who constructed that railway, which will corroborate what I say, that the railway crosses the river in several places.

1037. (*Mr. Harrison.*) I think that Mr. Bateman stated that he had not specially surveyed that portion of the district, but that from his general knowledge he had no doubt that sites might be obtained?—I examined the locality and I could not find any sites worth speaking of, except those in valleys which are already occupied by railways.

1038. (*Chairman.*) Do you consider that this particular district is full of metalliferous veins and mineral workings?—Yes, I do. In Mr. Bateman's pamphlet, he states that the district is free from metalliferous veins or other sources of objection, and I heard him make a similar statement in this room, and I can only say that some great oversight must have occurred, for it is not only full of metalliferous veins, but it abounds in mineral workings. There are no less than five lead mines within the drainage area of the southern portion. On the river Clywedog, about a mile and a half above Mr. Bateman's proposed reservoir at the village of Stay-a-little, there are two large lead mines and works draining into the river; one of them, which is called the Deliffy, is the richest mine in that country, it employs about 220 hands, and it is provided with washing and crushing machinery, and all the necessary adjuncts. About half a mile from that mine, higher up the valley, there is another lead mine and works called Dwngwm mine; it is not so extensive a mine as the first one, it occupies about 110 hands.

1039. (*Sir J. Thwaites.*) Are those mines worked by means of water power or steam?—The machinery is worked by water power, at least I was told so. I was not down close to the mine, but I was told so. On the river Afon Biga, draining into the river Clywedog, there is another lead mine and works, but what number of hands they employ or the extent of that mine I cannot tell you, because I forgot at the time to make inquiry into it, but it is indicated on the Ordnance sheets as a lead mine and works apparently as extensive as the other two which I have mentioned. Close adjoining the proposed reservoir at Stay-a-little there was a mining level being driven with the prospect of another mine being opened up. On the river Ceryst, at the upper end of the proposed reservoir at Trefeglwys, there are two lead mines, one of them is called the Van mine, it belongs to Earl Vane; it employs about 120 hands, and the mine is situated at the very water's edge. The mine is in a locality where it would be almost impossible to get rid of the drainage without pumping it away, it is likewise fitted with extensive washing and crushing machinery, and is worked by water power; immediately opposite to that, on the south side of the valley, there is another lead mine, which has not been worked for some years, but I was told that it was in contemplation shortly to reopen it. There are lead mines and works also in the vicinity all round, and in the northern portion of the drainage area, near Can-Office, a place was pointed out to me where a vein of copper has been recently opened, and which is said to afford a promise of success. In order that the question of the existence of the lead mines might not be dependent altogether on testimony, I have brought up from the Van mine immediately adjoining the upper end of Mr. Bateman's proposed reservoir at Trefeglwys, some specimens of ore (*producing a specimen*). This is the ore after it has been crushed and washed (*producing another specimen*). I also brought up with me a sample of the water taken from the river Ceryst, about half a mile below the point where it receives the drainage of the Van mine (*producing the same*). The river was a considerable stream. We have minerals in our district, but not to anything like the extent of this.

1040. Are there any lead mines in the northern

portion of the district?—There is a lead mine in the adjoining valley near the town of Llangynnog. It is not within the gathering area, but it is within the district which Mr. Bateman pointed out as the area to which he could extend his works, if necessary.

1041. (*Mr. Prestwich.*) In his evidence at page 11, Mr. Bateman mentioned the existence of lead mines in this district, but he did not think that that would affect his water as the water from those mines could be diverted?—I am speaking from his pamphlet in which he states, certainly, that there are no metalliferous veins within the districts from which he proposes to take water.

1042. At page 11 of his evidence, in answer to question No. 137, he says, "The 1·96 includes what "was coming down from lead works worked in that "valley, and which I have consequently rejected. "There are two or three mills there, and also the "sewage of Llanidloes, and therefore that 1·96 ought "not to be taken as a test"?—Mr. Bateman has mentioned that those mineral workings are on the river Severn, which he proposes to exclude from the scheme, but the lead mines and works which I have spoken of are not on the river Severn, and Mr. Bateman in his pamphlet certainly states that the districts he has selected are free from metalliferous veins.

1043. (*Mr. Harrison.*) He mentions, does he not, his taking water at Llanidloes bridge where there are some lead works?—That is the river Severn, which he proposes to exclude from the scheme.

1044. (*Chairman.*) You think that his project could not be extended, supposing that a larger area were required and the demand for water increased, as the district to the north-east of his scheme is highly cultivated and there are lead mines and mineral workings in the valley traversed by the river Tanat?—Yes; that is what I have shown the Commission on the map.

1045. And you think that it could not be extended in a southerly direction to the district bordering on the river Wye, because the valleys there also contain lead works and are occupied by existing or authorized railways, which would preclude the construction of reservoirs?—Yes.

1046. What objection have you to the sites of the proposed reservoirs?—I object to the sites of those reservoirs, first of all on account of the great destruction of property which would necessarily ensue. They contemplate altogether the submergence of nearly nine square miles of cultivated and populous country; for instance, the Llanwddyn reservoir in the valley of the Vryny, would cover 1,000 acres. That is the least valuable land of the whole; but it would submerge the entire village of Llanwddyn, containing from 30 to 40 houses with its church and adjoining graveyard, two Methodist chapels, and several detached farm-houses and cottages. The first reservoir on the river Banw just above Can-Office would cover 800 acres of valuable land and would submerge the village of Garthbibio with its new and handsome parsonage and schools attached, two Methodist chapels, and many detached farm-houses and cottages.

1047. Can you state the population of those two villages?—I cannot give the population, but the first village contains from 30 to 40 houses, and the village of Garthbibio contains, I should think, probably 30 houses. The second reservoir on the river Banw, just below Can-Office, would cover 600 acres of valuable land.

1048. In those two villages, one containing from 30 to 40 houses, and the other containing 30 houses, all the houses would be covered with water, would they not?—Yes, they would be all submerged. The great reservoir on the rivers Ceryst and Tarannon at Trefeglwys would cover 1,600 acres of valuable and highly cultivated land, and would submerge the entire village of Trefeglwys, containing probably 40 houses, with its recently newly re-erected church, the adjoining graveyard, the parsonage, two Methodist chapels, one of them having a small graveyard attached, and many valuable farm-houses and cottages. And most of these reservoirs would submerge the main lines of turnpike and other roads through their respective localities, as well as the various properties which I have just mentioned. And all those reservoirs are formed in clay valleys, and the sides are, for the most part, flat and sloping. If the water were to be preserved pure in them it would require an immense expenditure of money in artificially beaching them. They would have to be covered all over with stone, otherwise the wash of the water in those large reservoirs on the clay sides would keep the water perpetually turbid. I saw an instance of that recently in the Roundwood reservoir near Dublin, which was a small reservoir compared with these, covering only 420 acres, it has, however, flat clay sides, and the wash of the water on them was keeping the water in the reservoir quite turbid.

1049. (*Mr. Prestwich.*) I think that Mr. Bateman stated that there was only one of the valleys in which there was any large amount of clay?—There is plenty of clay for puddling, and the material is very admirable for that purpose. I also wish to state, with relation to these reservoirs, that from some observations which I made in the locality, I have reason to think that some of them, at all events two of the largest the reservoirs, one at Garthbibio, above Can-Office, and the large reservoir at Trefeglwys, will not contain nearly the amount of water at which their capacity is estimated. I think that some error of computation must have crept into the calculations. I may be wrong of course, but the result of my observations was to lead me to believe that those reservoirs would not contain nearly the amount of water which was mentioned in Mr. Bateman's paper.

1050. (*Sir J. Thwaites.*) Have you calculated the cubical contents?—I have not calculated the cubical contents myself, but I have satisfied myself that the dimensions and depth of water in those reservoirs could not be such as he says.

1051. (*Mr. Harrison.*) Have you had sections made of them?—No.

1052. You will recollect that I asked Mr. Bateman the question whether those calculations were based on actual survey, and that he said that as regards the reservoirs, they were entirely so?—Your question, as I understood it, was whether there was a section taken on the line of the embankments.

1053. You will not find that I refer to the line of the embankments; it was intended to be a general question?—That was my impression.

1054. (*Colonel Harness.*) What was the nature of your observations?—My observations were made with a very excellent aneroid barometer, it being perfectly steady at the time, and under such circumstances you could read within 5 feet with the greatest ease.

1055. (*Sir J. Thwaites.*) Have you any doubt as to the stability of the dam which Mr. Bateman proposes?—The localities are such that embankments could be made there perfectly well.

1056. (*Mr. Harrison.*) You stated, did you not, that you do not think there is any possible means of adding to the area from which water could be obtained?—Yes, I have made a statement to that effect.

1057. Did the possibility ever occur to you of putting a drift-way through to the west side of this watershed?—Yes. The whole of the western slopes of those hills are a mass of metalliferous veins and workings, and, therefore, I believe that no water fit for use could be obtained from that district. It is a notorious fact, that the whole of the western slopes of those mountains are covered with lead veins and lead works. You may see in this green area on the map that the mineral veins protrude into the drainage areas of several streams on the eastern side of the hills. It is there that those lead mines, which I have mentioned, occur.

1058. Excepting on that ground there would be no difficulty at all in doing it?—No.

1059. (*Chairman.*) Have you made any calculation as to the comparative cost of the water delivered in

R. Hassard, Esq.

20 Feb. 1867.

London between Mr. Bateman's project and your project?—Yes, I have prepared a table to that effect.

1060. Will you state shortly to the Commissioners the heads of that table?—I have added to the cost of Mr. Bateman's project in comparing it with ours what would be the annual cost of filtration capitalized, and what would be the outlay necessary for the construction of filters to put the two projects on terms of equality; and I estimate the cost of procuring 220,000,000 gallons daily from Wales, taking the total cost of that project, at 21,000,000*l.*; that is including 8,500,000*l.* for the purchase of the existing water companies' works and interests, and adding 1,500,000*l.* to Mr. Bateman's estimate, which would represent nearly the cost of the filters, &c., added to the cost of filtration capitalized at 20 years purchase, the water would then cost, delivered in London, 95,454*l.* per million gallons daily. From the lakes, if we delivered 250,000,000 gallons daily in London, our capital would be 22,000,000*l.*; adding as before 8,500,000*l.* to the 13,500,000*l.* of our gross outlay; that would bring the cost of water delivered in London to 88,000*l.* per million gallons. Then as our project is capable of bringing in 30,000,000 gallons a day more than the Welsh one, I take it that we deliver 220,000,000 gallons daily in London, and that we sell the other 30,000,000 gallons on the road. And supposing, in the first instance, that we sell 20,000,000 gallons daily at 10*l.* per million gallons, that would reduce our total outlay to 20,540,000*l.* A revenue of 73,000*l.* so derived from the sale of the water I have capitalized at 20 years purchase and deducted from the 22,000,000*l.*, which would be our gross outlay. That would bring the value of water delivered in London to 93,363*l.* per million gallons. Then from the lakes, supposing that 30,000,000 gallons were sold to other towns at the same rate, that would reduce the outlay to 19,810,000*l.*, and the cost of the water delivered in London to 90,045*l.* per million gallons as against 95,454*l.* from the Welsh district.

With the permission of the Commissioners I will hand in the following tables:—

TABLE showing what would be the Comparative Cost of procuring a Supply of 220,000,000 gallons of Water daily from Wales, and of 250,000,000 gallons daily from the Lakes, including the purchase of existing works, supposing, in the first instance, that no water is sold from the lake project to the intervening towns, and secondly, supposing that the 30,000,000 gallons of water which it is capable of supplying in excess of the Welsh project is so sold.

District.	Gallons daily.	Total cost.	Cost per million gallons daily.	Observations.
		£	£	
From Wales - - -	220,000,000	21,000,000	95,454	Cost of filters and filtration capitalized, taken at about 1,500,000*l.* and purchase of existing works at 8,500,000*l.*
From the Lakes - - -	250,000,000	22,000,000	88,000	Purchase of existing works taken at 8,500,000*l.*, and also in the following case.
From the Lakes, supposing 20,000,000 gallons sold daily to other towns at 10*l.* per million gallons.	230,000,000	20,440,000*	—	* A revenue of 73,000*l.* capitalized and deducted from gross outlay of 22,000,000*l.*
From the Lakes, supposing 30,000,000 gallons sold daily to other towns at 10*l.* per million gallons.	220,000,000	19,810,000†	—	† A revenue of 109,500*l.* capitalized and deducted from gross outlay of 22,000,000*l.*

TABLE showing the Gross Cost for Water which has been incurred in Liverpool, Manchester, and Glasgow, including the purchase of existing works, as compared with that which would be incurred in London for a new supply from the Lakes.

	Gallons daily.	Cost.	Per million gallons daily.	Observations.
		£	£	
In Liverpool - - -	16,500,000	1,900,000	115,115	
In Manchester - - -	25,000,000	1,500,000	60,000	
In Glasgow - - - -	27,000,000	1,600,000	59,260	
Ditto, when full supply is obtained from Lough Katrine.	53,500,000	1,800,000	33,645	
In London, with water supply from the lakes.	250,000,000	22,000,000	88,000	Purchase of existing works taken at 8,500,000*l.* and also in the two following cases.
In London, if 25,000,000 gallons were sold daily to other towns at 10*l.* per million gallons, the revenue so obtained capitalized and deducted from outlay.	225,000,000	20,175,000*	—	* Revenue capitalized 1,825,000*l.* and deducted from 22,000,000*l.*
Ditto, if 50,000,000 gallons were sold in same way.	200,000,000	18,350,000†	—	† Revenue capitalized 3,650,000*l.* and deducted from 22,000,000*l.*

Perhaps I might be allowed to observe that if the Commission decide on making a personal examination of these localities (and I scarcely see how a satisfactory solution can otherwise be arrived at), and as the waters to be derived from both districts are essentially flood waters, it would be almost necessary that such an investigation or examination should take place in weather that was moderately wet.

LONDON AND PROVINCIAL WATER SUPPLY. LAKE PROJECT.

ABSTRACT ESTIMATE OF WORKS FOR SUPPLYING 250,000,000 GALLONS DAILY.

Reservoirs, conduits, and works of collection	£1,013,000
Tunnel under Kirkstone Pass: 2 miles at 80,000*l.*, 4 miles at 50,000*l.*	360,000
Aqueduct to London	9,806,260
Regulating Reservoirs at Edgware	500,000
	£11,679,260
Interest on borrowed money and expenses during and attendant on construction	1,820,740
	£13,500,000

ESTIMATE FOR RESERVOIRS AND WORKS OF COLLECTION.

3½ miles of open conduit from Coopers Green to Swindale at 4,750*l.* per mile	£16,625
2⅔ miles of open conduit from Swindale to Haweswater at 5,400*l.* per mile	14,175
Haweswater Reservoir	73,500
4 miles of open Conduit from Haweswater to Heltondale Beck at 4,000*l.* per mile	16,000
Sluices and weir at Askham	5,000
5 miles of open conduit from river Lowther to Pooley Bridge at 7,500*l.* per mile	37,500
1½ miles of open conduit, from Ulleswater to Dacre Beck at 5,000*l.* per mile	7,500
Ulleswater Reservoir	100,000
7½ miles of open conduit from Barrow Beck to Thirlmere at 6,000*l.* per mile	45,000
2 miles of Tunnel on ditto 10ft. × 10ft. at 26,400*l.* per mile	52,800
Thirlmere Reservoir	83,000
Conduit to Ulleswater 5 miles at 7,500*l.*	37,500
7½ miles of Tunnel 12ft. × 12ft. at 30,000*l.*	225,000
10 miles of catchwater drain from Thirlmere to Borrowdale, averaging 2,500*l.* per mile	25,000
⅓rd mile small tunnel 8 ft. × 8ft.	7,500
4¼ miles of catchwater drains from Thirlmere to Easedale Tarn, averaging 2,500*l.* per mile	10,625
2 miles small tunnels, 6ft. × 6ft.	21,120
St. John's Beck compensation reservoir	45,000
Carried forward	£822,845

Brought forward	£822,845
Works for diversion of mining drainage	35,000
	857,845
Contingencies 10 per cent.	85,784
	943,629
Martindale and Swindale auxiliary reservoirs, including contingencies, if hereafter required	69,371
	£1,013,000

HAWESWATER RESERVOIR.

370 acres of land at 75*l.*	£27,750
Rebuilding houses, &c.	6,000
4 miles of new road alongside lake, at 2,000*l.*	8,000
Embankment, 127,500 cubic yards, to cover puddling, pitching, soiling, &c., at 2*s.*	12,750
Waste weir	3,000
Eduction tunnel, pipes, valves, gauges, &c.	16,000
	£73,500

THIRLMERE RESERVOIR.

400 acres of land at 75*l.*	£30,000
Rebuilding houses, &c.	8,000
2½ miles of new road at 2,000*l.*	5,000
Embankment, 150,000 cubic yards, to cover puddling, pitching, soiling, &c., at 2*s.*	15,000
Eduction tunnel, pipes, valves, gauges, &c.	25,000
	£83,000

ULLESWATER RESERVOIR.

76 acres of land at 80*l.*	£6,080
4 miles raising and altering roads at 2,500*l.*	10,000
Embankment at Eusemere Hill, to cover pitching and puddling 10,000 cubic yards at 4*s.*	2,000
Pipes, valves, syphons, and eduction apparatus	60,000
	£78,080

Say 100,000*l.* to cover damage and compensation.

R. Hassard, Esq.

20 Feb. 1867.

The witness withdrew.

Adjourned to to-morrow at 11 o'clock.

Thursday, 21st February 1867.

PRESENT:

HIS GRACE THE DUKE OF RICHMOND IN THE CHAIR.

Sir JOHN THWAITES.
Colonel HARNESS.
Alderman Sir BENJAMIN PHILLIPS.
THOMAS ELLIOT HARRISON, Esq.
JOSEPH PRESTWICH, Esq.

THOMAS DALE, Esq., examined.

T. Dale, Esq.

21 Feb. 1867.

1061. (*Chairman.*) You are, I believe, a civil engineer?—I am.

1062. And the engineer to the Corporation Waterworks of Hull?—I am.

1063. And you have turned your attention, have you not, to the general question of the supply of water?—I have.

1064. You have, I believe, prepared a scheme for supplying the towns of Lancashire and Yorkshire with water from the lake districts of Cumberland and Westmoreland?—I have.

1065. Has this scheme been under consideration by you since the end of 1865?—It has, and for *several years* previous.

1066. Before going into the question of the amount of the supply, what, in your opinion, is the quality of water most desirable for the supply of large towns?—Soft water.

1067. How would you define soft water, or is there any means of defining it?—It is generally by engineers called soft water up to about four degrees of hardness; some admit six degrees of hardness, but I should call it soft water up to and including four degrees of hardness.

1068. Then any water in which there was upwards of four degrees of hardness you would consider as hard water, and not desirable for the supply of towns if other could be obtained?—I should.

1069. You state that you prefer water to be soft for the use of the populations in towns generally, will you give the Commissioners your reasons for preferring soft water to hard?—For domestic purposes, in

T. Dale, Esq.
21 Feb. 1867.

the first place, there is a very great saving in the use of soap; for instance, I will take a chalk water of 17 degrees of hardness, which is about the number of degrees of hardness that the water at the present time supplied to the town of Hull is; a degree of hardness according to Clarke's test is one grain of chalk to a gallon of water. The quantity of soap necessary to soften, say one degree in 100 gallons of water, would be equal to about two ounces, that is to say, about 2 lbs. 2 oz. of soap would be required to soften 17 degrees of hardness.

1070. That is to say, it would take that amount of soap to bring 17 degrees down to four degrees?—No, down to 0, or, in other words, in 100 gallons of water it would require 2 lbs. and 2 oz. of soap to reduce water of 17 degrees of hardness down to distilled water.

1071. That is your first reason, that soft water produces a saving in the quantity of soap used for all domestic purposes?—Yes, that is for washing purposes. Then again in the use of water for making tea and coffee also there is a great saving effected, but I am not prepared to say to what extent.

1072. (*Sir J. Thwaites.*) Has your attention been turned to the saving that would result in culinary operations generally?—It has not; I can only say that it is admitted that there is a great saving. Soyer had some statistics on the subject, with regard to the boiling of vegetables, which I have seen but I have forgotten them.

1073. (*Sir B. Phillips.*) Have you taken brewing into consideration at all?—No, I have merely looked at the matter generally, but there is a great saving in the matter of brewing.

1074. Have you any idea as to what the saving is?—I am not prepared with statistics. The only data on which I have to go in looking at this matter are the calculations and figures which were gone into by Mr. Bateman at the time that the Loch Katrine water was introduced into Glasgow. According to Mr. Bateman there was a saving in the first year of some 36,000*l.* through the use of the soft waters of Loch Katrine (they being something over one degree of hardness,) over the use of the Clyde water of seven degrees of hardness. And in looking just casually at this point I have taken that fact as an inducement in presenting my scheme to the various corporations to induce them to adopt it, and to attract the attention also of manufacturers. I have taken the population of Glasgow at 400,000; Mr. Bateman has gone into the matter very carefully, and he has shown that there was a saving of 36,000*l.* a year upon a population of 400,000 persons. He says, "This was by the substitution of water of one degree of hardness as "compared with the water previously used from the "Clyde, which varied from seven to nine degrees of "hardness." Then let us look at the different manufacturing towns, such as Leeds, Bradford, Wakefield, Dewsbury, Halifax, Huddersfield, &c., where worsted, cloth, stuff, silks, bleach works, dye houses, and other descriptions of manufactories exist so extensively, and where immense sums of money are expended annually in the softening and neutralizing process of the waters at present used by the use of large quantities of drugs and chemicals. By substituting this soft lake water in lieu of the waters at present used, which range from seven to 14 or 15 degrees of hardness, there would be an immense saving of, I assume, upwards of 200,000*l.* annually. But I consider that there would be three times the amount saved in adopting this water for those different purposes, even in a manufacturing point of view. That can only be gone into by obtaining the necessary statistics, which I have applied for in one or two instances, but having been called upon so quickly by this Commission I have not been able to get them together.

1075. (*Sir B. Phillips.*) The districts through which you propose to bring water are the manufacturing districts of Yorkshire, are they not?—Yes.

1076. And you have spoken of certain manufactures there, but your figures are assumption only, are they not?—Nothing more.

1077. You are aware, are you not, that in this district there is a very large number of spinners who use considerable quantities of water in washing their yarns?—Yes.

1078. Has that at all attracted your attention in any way?—I include that in the worsted manufacture, but I have not gone into detail in those matters; I have not the statistics.

1079. (*Sir J. Thwaites.*) Has your attention been turned to the dyeing department of industry, as to the fact of soft water being very superior to hard water?—I have had some conversation with dyers on the subject, and I know that it is most important to dyers; they produce, I understand, a more brilliant colour.

1080. But you have personally no experience upon that point?—No, I have not. Then again, with regard to cloth, I have inquired among the cloth manufacturers and I find that in dressing the cloth the soft waters give a better finish to the cloth than hard water.

1081. (*Sir B. Phillips.*) Your evidence simply goes to this effect, that soft water for all manufacturing purposes is much more desirable than hard water?—That is so.

1082. But you are not in possession of any statistics as to facts?—I am not.

1083. (*Mr. Prestwich.*) Are you aware that when some years ago the question of hard and soft water was discussed in Lyons the dyers there gave the preference to waters containing a very large proportion of carbonate of lime, that is to say very hard water?—I am not aware of that.

1084. (*Sir J. Thwaites.*) In your district is not the manufacture of cloth very extensive?—Not in Hull, but in Yorkshire it is very extensive indeed.

1085. Is the scouring process carried on by means of soap, or how do they get rid of the oil from the cloth?—I am not aware; I am not acquainted with the cloth manufacture.

1086. They use a great deal of oil in the manufacture which must be washed out?—Yes, it must be washed out with soap.

1087. Then the question of hardness or softness would be an element of great consideration, would it not, to the manufacturers of cloth?—Very great.

1088. (*Chairman.*) What is the amount per head per day that you would consider a proper quantity for the population which you are contemplating supplying?—I have put down about 90 gallons per head, not including trade purposes; that is to say, in carrying out the whole of the scheme, speaking prospectively.

1089. My question is, what amount of water do you think each individual would consume or ought to consume?—Allowing for domestic purposes, I put down 20 gallons per head.

1090. (*Sir J. Thwaites.*) Is the plus 20 up to 90 for manufacturing purposes?—In dealing with the whole of this scheme I propose to construct works looking prospectively to the advance of the populations and the requirements of future populations. The total then, according to the works which I propose to be constructed, is 90 gallons per head, looking forward to a further period of, say, 50 years.

1091. (*Sir B. Phillips.*) You mean, do you not, 90 gallons per head upon the present population?—Yes; take 90 gallons per head upon the present population, looking forward to the advance, the quantity of about 20 gallons per head would be allowed in, say, 50 years time.

1092. (*Sir J. Thwaites.*) Have you taken that as the basis of your calculation?—I have.

1093. Do you calculate the prospective increase of the population for any given number of years?—I have taken the matter roughly out.

1094. And does your scheme provide for the increased population of 50 years?—Yes, for 50 years or beyond. (The total population is about 1,500,000.)

1095. Taking a mixed population, a considerable amount of consumption for domestic purposes and a reasonable amount for trade purposes, what in such a case would be your view of the quantity per head ?—30 gallons per head.

1096. What is the quantity which you are supplying to the inhabitants of Hull ? — Including trade and domestic purposes about 32 gallons per head.

1097. Are most of the houses supplied with water in Hull ?—All the houses are supplied with water.

1098. Are not several of the courts there supplied with stand cocks, the water not being laid on to the individual houses ?—The whole of the houses are supplied with water, but in courts the mode is to put stand pipes and the parties go to the stand pipes and draw their water.

1099. Take a court, for example, of 40 houses, I presume the water is not supplied to every house, but they have one common source of supply at the head of the court which all have a right to resort to ?—Yes, that is the plan in some of the courts.

1100. Then the consumption per head of the inhabitants of those 40 houses must be considerably under 20 gallons per head, must it not ?—Taking the average the people inhabiting courts use a great quantity of water. When there is a stand pipe open to children with people going to it from time to time there is more leakage with a stand pipe in a court than there would be if there was a tap at each house a the water taken inside, and therefore I should say that they use on an average as much water as in the houses where the pipes are laid on direct.

1101. Have you tested that by comparison ?—I have not, that could only be done by fixing a meter.

1102. Is it the habit of the landlords in Hull to go on giving an independent water supply to the houses, or is that system of supplying from one source a large number of houses continued ?—Only in courts where there are some 10 or 20 houses ; if it is a large court there are two pipes laid down, for instance, there is a stand pipe and tap put down to perhaps three or four houses, and there is another tap for three or four others, and so on.

1103. Are the houses in Hull, other than those in courts, supplied independently ?—They are supplied independently ; pipes are put in the service pipes, and those pipes are taken in direct into the houses.

1104. Have they cisterns or have they a constant supply ?—A part of the town has a constant supply, and the other part a constant and intermittent supply.

1105. What are your reasons for having part constant and part intermittent ?—The river Hull divides one portion of the town from the other, the one lying to the eastward and the other to the westward, the greatest population is to the westward and includes the old town. The pipes which were laid to the eastern district were put in a better condition from time to time so as to bear the night pressure of the constant supply ; whereas the pipes are more dilapidated on the western side, and we are at the present time taking up the old service pipes and putting in new ones in the different streets and in those cases we adopt the constant supply and the night pressure is left on.

1106. Are we to understand that you have had no reason, other than the insufficiency of your plant to stand the pressure, why you have not a constant supply all over the town ?—That is the case.

1107. And we are also to understand that you are in course of arranging a constant supply all over the town as you are relaying fresh pipes in lieu of those of insufficient strength to resist the night pressure ?—Yes, we are.

1108. Have you experienced any inconvenience arising from the constant supply ?—None at all ; far from it ; there is far less leakage I should say, and I have tested it in fact. I should say that on the eastern portion of the town there is a saving of 25 per cent., or say 20 per cent. to be on the safe side, in the leakage, compared to what there is on the other side of the town.

1109. Is that due to the constant pressure and the the absence of cisterns with ball taps, or is it due to the extravagant escape in consequence of the imperfect plant which you have on the other side of the water ? —It is due to one or two causes, and I may perhaps state them. In the first place, in the intermittent, if any water is wanted in a house the servant goes to the tap and turns it on, and leaves it so, and when the supply turncocks have shut it off at night, perhaps the tap is turned and left open ; in the morning about 6 o'clock the turncocks turn on the water and the people perhaps do not require it until 7 or half-past 7 o'clock for breakfast, and the taps are left running and great quantities of water run away in that way. There is a great loss of water on that account, whereas on the other side of the river, on the eastern portion where the constant supply is on, when they turn the tap and draw water, for convenience sake they shut it off again when they have got their water.

1110. Have you tested by any meter the result of this constant supply as compared with the intermittent system ?—I have tested it not by meter but in this way. We have large Cornish engines at the works, and the water is pumped into the mains at a pressure varying during the day from 60 feet to 110 feet. The works are on the western side of the river Hull, and the principal main proceeds from the works for a distance of some 200 or 300 yards, say 200 yards, and ono branch then passes right away to supply the western portion, and the other one at once crosses the river Hull to supply the eastern portion, and we have two sluices fixed, so that we can shut off the eastern portion of the supply at any time, or we can shut off the western portion and leave the eastern portion on. Then in order to test this I have shut off the west side of the town when the engine has been working say at a certain speed, with a pressure equal to some 60 or 70 feet, and with a draught on both lines of main for both sides of the town. Then when we shut off the western portion we have a certain number of manufactories using a certain quantity of water, and so much for domestic purposes. We then take the inhabitants that are on the southern or the western side, and compare the quantity of water supplied to them with the quantity of water pumped by the engine for the eastern side by itself. Then we shut off the eastern side and make the same comparison on the western side, and the engine gives another result with the same pressure of water in the mains against the same numbers of inhabitants, and making due allowance for the quantities used in trade, and the result shows at once what the saving is by the constant system as compared with the intermittent system, which I say is 20 per cent.

1111. Have you had any complaint from the inhabitants with regard to the change of system ?—The inhabitants are continually crying out for a constant supply, they prefer it to intermittent.

1112. Have you observed or has any officer connected with the corporation reported to that body as to the result upon the public health by the removal of the ordinary receptacles for water and adopting the constant supply ?—That had not been gone into, but there are many objections to the intermittent water supply. When you have a constant supply in the town the mains are continually charged with water, but I have observed that when you have an intermittent supply, when the water is abstracted and run completely out of the pipes a certain vacuum is produced in the pipes and something must rush in to fill it. The taps which are generally fixed for domestic purposes are fixed invariably over sink stones. Then with regard to the pipes themselves, if a leakage takes place in the pipes the water generally oozes through and comes to the surface, and you can discover it and you immediately make good the joint and stop the leakage ; but there are instances, and many to my knowledge, which will occur whenever pipes and services are laid, where the joints have to cross sewers or to come very near places where there is loose materials round the sewers and in the passage of the pipes over those parts leakages will

T. Dale, Esq.

21 Feb. 1867.

occur and the water runs away down the sewers, and you cannot discover the leakage.

1113. Does leakage occur more under the system of a constant supply or under the system of an intermittent supply?—It occurs more with the intermittent than it does with the constant supply.

1114. Is that one of the results that give you the 20 per cent. saving?—It is one of the results. What I wish to point out is this, that after the waters have rushed out of the pipes which have been leaking during the day, the foul gases in the sewers and the foul gases over the sinks rush into the pipes, and are absorbed into the vacuum.

1115. Have you any special arrangement with regard to your watercloscts under the constant supply system?—None in Hull; there is no charge for watercloscts.

1116. In adopting the constant system you must have a distinct arrangement from that which is usual where the water is contained in a cistern; do they use cisterns for watercloset purposes, or have they simply an ordinary pipe to turn on and off?—They use cisterns, and the cisterns are fixed over the watercloscts as before.

1117. Is the use of cisterns general?—It is general for watercloscts.

1118. Would there be no means of getting rid of those cisterns, or, if so, would that tend to waste, do you think?—If you get rid of the cistern you must convey your water with a tap over the watercloset, and if you do that you then have a direct communication when the water is off for the gases of your watercloset to rush up your pipe into the pipe which is supplying the watercloset; but if you have a tank above, that tank provides at once, by the ball tap, a means of protecting the mouth of the feeding pipe to the closet.

1119. A pipe charged with water would not admit the gases which you refer to?—No, but those pipes are shut off occasionally for repairs.

1120. (*Chairman.*) You have given us your opinion, and stated the reasons why you think that the water supplied to the populations of towns should be soft, and of course of the greatest possible purity; it is scarcely necessary for me to ask you that which I suppose all people are agreed about, that in order to ensure this the gathering grounds must be free from all impurity, and be protected against all agricultural and trade pollutions, and especially the sewage of towns?—That is so, of course.

1121. And would you also think it desirable that there should be an unlimited abundance of supply?—Yes.

1122. As large a supply as you can get over and above what you want to abstract at the present time?—Yes, it is desirable on several accounts. In the first place, as regards cleanliness, I think the desirableness of it was proved in the first and second reports of the Commission of 1844 and 1845, before whom evidence was produced to show that from the economizing of water in filthy courts and alleys from people washing their clothes twice over, and from the miasma arising from stopped up drains and choked up sewers, for want of flushing, considerable disease and death were occasioned.

1123. When you speak of economizing water, what do you mean by that expression?—Where towns are invariably short of the quantities required to be supplied, the waters are economized by intermittent supplies; they supply a certain quantity perhaps for a few hours of the day for the use of the inhabitants.

1124. Do you mean that the water used gets very dirty, whereas if they had a cheaper supply they would use more of it, and therefore it would be cleaner for domestic purposes?—Yes, that is what I mean.

1125. When you say that they washed their clothes twice over, you mean that they use the same water twice which they would otherwise use but once?—Yes.

1126. Can you give us your views with regard to what the description of the gathering ground should be?—My views on that subject are these. Mountainous regions, such as those gathering grounds which I propose should be utilized, namely, the Cumberland and Westmoreland lake districts, are fit for no other purpose than as gathering grounds; they can be made no use of by the agriculturist nor the manufacturer; they are mostly bare rocks that are well adapted for gathering grounds. Gathering grounds, under other circumstances, are generally chosen by towns in the immediate localities of the towns, and they monopolize the waters of a district which should be used for agricultural and manufacturing purposes.

1127. Are we to understand you to state that on the grounds which surround Ullswater and which surround Haweswater, which is the district from which you propose to take your water, there is no agricultural population?—Very little, excepting by the sides of the lakes. There are a few farms by the sides of the lakes, and there is some little pasture land there, but very little. The rest is covered with heath and moss and bare rocks.

1128. Would not the heath and moss which you state are there be likely to produce organic impurities in the water?—I should say not.

1129. Do you think that that which is commonly called in those countries moss water is not necessarily an impure water, although it may be a dark coloured water?—There has been a difference of opinion, I think, upon that subject.

1130. What is your opinion as to the quality of the water which would be collected from a peaty and moss district?—I should call peaty water impure water, and I should say that portions of organic matter would be found in peaty water.

1131. And as such injurious to health?—Yes, injurious to health to some extent.

1132. Do I understand you that this ground of Haweswater and Ullswater, which you intend to utilize for the purposes of your supply, is a peaty and moss district in any part of it?—I believe there are some small portions on Bampton common that are peaty, but peat, in my opinion, under some circumstances, and in some positions, is not so injurious to water falling upon it as in other positions. If you have a boggy low district where the waters lie and stagnate, they soon become impure when brought in contact with bog or peat under such conditions; but where the peat lies on a precipitous area, or the waters are continually passing off and discharging themselves, the peat itself is soon cleansed of its organic matter.

1133. On what description of ground in the area from which you propose to take the water does this peat lie?—I have not noticed particularly. I have not looked into the matter in detail sufficiently to answer the question.

1134. Have you made any personal inspection of the ground which you have marked upon your plan as the ground from which you intend to take the water?—I have.

1135. But not sufficiently accurately to state which part of it is peat and which is not?—No, I have not. I speak of it generally.

1136. (*Mr. Prestwich.*) In your pamphlet you give an analysis of the lake water by Professor Way, which apparently is the same analysis as he furnished to Mr. Hemans. Have you had any independent analysis made of those waters?—No, we have taken them as good soft waters.

1137. (*Sir J. Thwaites.*) Do you state that you have walked that district?—I have been in that district.

1138. And you think that on Bampton common there is peat?—There is some little peat there.

1139. Is there not a very large tract of peat there going down towards Bampton?—I have not noticed it so as to speak to the quantity.

1140. Did you notice in going over Martindale common a tract of peat?—There are some portions

dotted round there, but I have not gone into the matter sufficiently to notice as to the quantity.

1141. But you walked over it, I suppose, for the purpose of ascertaining whether it was a proper gathering ground for your water?—Yes, I have gone over the whole district, but not so as to enable me to speak, except generally.

1142. (*Chairman.*) But as to the quality of this water, which you say is good soft water, and the sort of water which you desire to get, you have taken that, as you say, from the returns furnished to Mr. Hemans by Professor Way, and you have assumed all that is so stated to be correct?—Yes, so far as this analysis goes, but I consider that it is a soft water. This analysis of Professor Way's was taken evidently under certain circumstances, and not at a favourable time, and I simply inserted it in my second address to the governing bodies of towns in order to induce them to go there. I may observe that I have taken the matter up simply at my own expense, and as expressing merely general views. I have not had sufficient time to mature them, neither could I afford to do so as a private individual, therefore I have approached the subject as near as I possibly could with certain data with a view to induce those governing bodies to go to the lake district for their water supply. But I was about to state that I assumed, first of all, before this analysis was taken, that those waters were equal to the Loch Katrine water in softness without going to the expense of an analysis.

1143. What grounds had you which induced you to assume that the waters proposed to be taken from Ullswater and Haweswater were of the same quality as the Loch Katrine water?—Because the gathering ground being composed of the lower silurian rocks, when the rain fell on them there would be no mineral impregnation to harden the waters, and they would be as soft as the Loch Katrine waters.

1144. (*Mr. Prestwich.*) They are very similar gathering grounds, are they not, as far as regards the geological structure of the country?—Very similar.

1145. (*Chairman.*) Have you anything to state to Commissioners upon the failure of the sources of supply to various towns?—It is some 15 years ago since this idea first entered my head as to supplying towns with water from mountainous districts, and especially from Westmoreland and Cumberland, and my attention was drawn to it from the continual demand made for water and the insufficiency of the water supplied to different towns. I may point out, first of all, the supply to Liverpool as a failure; up to 1850 the water supply of Liverpool was in the hands of several companies, and was derived from the new red sandstone. In that year the waterworks were purchased by the corporation, who felt desirous of extending their works. They were presented with three different schemes: one was by Mr. Hawksley, the Rivington scheme; the second one was by Mr. Newlands and Mr. Simpson, who went for an extension of their present source from the red sandstone supply; and the next one, which no doubt was the best, was by Mr. Rawlinson, who proposed the Bala lake. Those schemes were referred to Mr. Robert Stephenson, who held a court of inquiry; he made a series of experiments and received a large mass of evidence, and the council on this report determined to carry out the works at Rivington.

1146. The Commission do not wish to inquire into the various schemes which have been before the public for the supply of Liverpool; we will take it as a matter of history that Liverpool is supplied now from a certain district?—I want to show the failure both in quantity and quality. The Pike scheme was to have supplied 25,000,000 gallons per day, and the pumping was to be done away with, and the amount that was expended was one and a half millions of money, but that quantity has not been supplied, and the quality has not been desirable, and therefore that source has failed. I have statistics to show that if necessary.

1147. What you mean is that in those towns which were proposed to be supplied from districts near to them, the supply has not kept up to the demand, and that therefore you would wish to go to a larger area and a mountainous district, where you think the supply would be so to speak unlimited?—That is my view of the case; Leeds is in the same position, and in that case the water supply there has failed in quality. The Pollution of Rivers Commission, I think, have had evidence sufficient to show Leeds does not suffer from quantity; they have power to pump 6,000,000 gallons a day from the river Wharfe.

1148. And you are of opinion that the mountainous districts of Cumberland and Westmoreland will supply both the quantity and the quality that are necessary for all those towns which are now not supplied in a satisfactory manner, some as regards quantity and quality?—That is my view of it.

1149. (*Sir B. Phillips.*) How is Halifax supplied at this moment?—Halifax is supplied from gravitation from catch water areas in the locality, I think, from the millstone grit.

1150. (*Chairman.*) You object also, do you not, to supplies from rivers and streams, because they are open to pollution as they pass through the country?—Yes.

1151. And you propose to get your water from Ullswater and Haweswater?—I do. (*The witness exhibited plans. See Appendices Q (1) and Q (2).*)

1152. Ullswater being 477 feet above the Ordnance datum, and Haweswater 694 feet?—Yes, those are the levels.

1153. And your scheme proposes to supply water to 20 towns of Lancashire and Yorkshire to the amount of 131,000,000 gallons a day?—Yes, for domestic purposes, taking the population at about 1,500,000.

The following is a list of the towns, and the quantities which my scheme proposes to supply:—

	gallons.
Lancaster	2 millions.
Preston	8 ,,
Wigan	4 ,,
Dewsbury	3 ,,
Wakefield	3 ,,
Liverpool	40 ,,
Leeds	15 ,,
Bingley	1 ,,
Kendal	2 ,,
Bolton	8 ,,
Blackburn	6 ,,
Keighley	2 ,,
Bradford	10 ,,
Huddersfield	4 ,,
Burnley	4 ,,
Rochdale	4 ,,
Halifax	4 ,,
Colne	1 ,,
Bury	8 ,,

1154. And you also propose by the same scheme to supply many small towns and districts contiguous to your main trunk pipes, over and above those which you have given in that list?—I do.

1155. And do you also propose to give to the whole of those towns water for manufacturing purposes?—I do.

1156. What is the amount of water which you propose to abstract daily from the lake districts?—The pipes that I propose are intended to have capacity of discharge at the rate of 150,000,000 gallons per day, and I deal with it in this way, I propose to raise Ullswater 10 feet above its present level.

1157. How do you purpose to raise it?—By a dam at the foot at Pooley bridge, by doing so I should impound an extra quantity over and above what is in the lake at its natural level of 7,985,000,000 gallons, then if I lower the lake from its present level, at five feet, which is the depth at which I propose to draw off the water, that would produce 2,915,000,000 gallons; affording when the lake is raised 10 feet above its present level or total storage of 10,900,000,000 gallons. Haweswater I propose to raise by an embankment 30

T. Dale, Esq.

21 Feb. 1867.

feet, and that would impound an extra quantity of 4,100,000,000 gallons by a dam at the Lowther end.

1158. (*Sir J. Thwaites.*) Before going from Ullswater, you propose, you say, to raise it 10 feet, have you carefully examined the banks of the lake?—I have looked round the banks of the lake, but I have not made a survey of it.

1159. Do you not know that the western shore is studded with houses of very great value; I mean the upper part towards Patterdale?—I believe there are houses there.

1160. You would flood them by raising the lake 10 feet, would you not?—Some of them would be flooded, but not many; I have not made a survey so as to be able to state the number of houses or the value of the property; I have not gone into that question so far. In going into this matter, I have gone into it simply generally just to show the feasibility of the scheme.

1161. A part of a feasibility of a scheme would be its reasonable cost, would it not?—That I am prepared to show, because I have allowed liberally in the estimates.

1162. But you have not made an estimate at all have you for the destruction of property in Ullswater?—I have allowed a sum for contingencies in which I have included roughly the value of the land and the cost of removing a number of houses.

1163. Surely this is not a contingency, it is a substantial part of the scheme when you are flooding houses and property to the extent that you are in this case?—In going into my estimate I have allowed roughly for the value of lands, and the moving of houses, and the contingencies arising out therefrom.

1164. Is that result based on anything like a minute calculation of the value of the property which you do affect?—It is not.

1165. Then what is it worth?—It is impossible in approaching a scheme of this sort to go into minutia.

1166. But as an engineer you usually add a certain sum for contingencies; that is to say, a sum which will cover matters over which you have no control and which you cannot at the time foresee; but here you propose to raise the surface level of the lake so as to flood and destroy a large quantity of valuable land and very many valuable houses, and yet you have made no estimate of the cost of it?—For that and other matters I have allowed a certain amount which I have put together in a lump-sum. I have not gone into the minutia, such as the taking down of houses and removing them.

1167. Then you are not at present acquainted with the number of acres that would be flooded by raising the surface of that lake 10 feet?—I calculate that there are some 300 acres which would be submerged.

1168. (*Mr. Harrison.*) What is the amount which you have allowed in your estimate for those contingencies?—I have put them in with the towns connexions and the works at the lakes at an amount which works out roughly at 255,000*l.*

1169. (*Mr. Prestwich.*) What is the extent of the drainage area of Ullswater itself and of Haweswater also?—The catchwater area of Ullswater is 39,680 acres, including the area of the lake, which is 2,142 acres. The Haweswater catchwater area, including the becks and streams, is 24,320 acres, including the area of the lake, which is 330 acres.

1170. (*Sir J. Thwaites.*) You propose do you not to raise Haweswater 30 feet in level?—I do.

1171. Are you aware that there is a discharge into the upper part of Ullswater of slate washing?—I am aware that there is at Glenridding.

1172. How do you propose to deal with that?—I have thought of that subject and my first idea was to intercept those waters, carrying them into the river Eamont below the foot of the lake, but on more maturely considering the question there is only one way to deal with it if it is to be adopted as a public gathering ground, and that is, the lead mines ought to be purchased. In fact, my own view is that the whole of the gathering ground ought to be purchased, and that no lead mines should be worked in the neighbourhood.

1173. That is not a part of your estimate, I presume?—No, that is not a part of my estimate, but only my view.

1174. (*Chairman.*) That is to say, if a perfect scheme for a perfect water supply to the towns of Lancashire and Yorkshire were to be carried out there would follow a necessity for buying the whole of that country?—I should recommend that the whole of that gathering ground be secured and guaranteed for all time to come against mining or any other purpose of that nature, either by purchase or by lease or by some other mode.

1175. What sum of money would purchase 62 square miles of land, or 70,000 acres?—At the present time the owners are receiving very little from that property, it is only used for game, it is fit for nothing else.

1176. In some portions there are lead mines which we assume to be valuable; have you estimated their value at all?—I have not made any estimate, but those are my views.

1177. I do not mean a close estimate, but have you turned over in your mind what would be the probable or possible cost of buying 62 square miles at Ullswater and 38 square miles at Haweswater, making upwards of 100 square miles?—I have not.

1178. Would not the feasibility of a scheme very much depend upon what it would cost?—Of course.

1179. But if in order to make this a perfect scheme the necessity would follow of buying this land, the purchase of 100 square miles would come to something very large, and the value of the water would be very much enhanced by what you have to pay for the ground, would it not?—Perhaps I may be wrong in going so far as to recommend the purchase of the whole area of the gathering grounds, but if they are adopted as gathering grounds, and I do not know where the towns can get water from elsewhere, a more economical means might be adopted by securing those gathering grounds from being used for lead mining, or if lead mines are searched for and worked there, proper means should be adopted for carrying away the refuse waters used at those mines, either into the river Eamont or to some other place, so as to keep the water from polluting the reservoirs of that lake or the ground around it.

1180. That is to say, you think that Parliament should step in and say either that no lead mines should be worked within an area of 100 square miles, or that the water used in the lead mines should be carried into other rivers—but then, what would become of the people who lived on the river Eamont and those other rivers and who might have property there?—There is the difficulty I grant.

1181. Do you think it right that Parliament should step in and say, that no pollution from the lead mines shall be put into Ullswater or Haweswater, but that it shall all be carried into and convert the river Eamont into a sort of common sewer of the district?—I do not think that that would be right.

1182. (*Sir J. Thwaites.*) How are the people at Penrith to get their supply?—They would pump the water into the town. I said that the present lead mines ought to be purchased and that Parliament should step in and grant powers such as to prevent all future working of lead mines, the waters of which would find their way into the river Eamont; in fact, the lead mining should be stopped altogether.

1183. (*Chairman.*) Supposing I had property in that district, would it not be rather arbitrary in Parliament to step in and say, "You shall not work your "mines, you may have there valuable property which "might produce you thousands and thousands a year," and we say, "You may stay above ground and do "what you like, but you must not dip into the bowels "of the earth to extract that which would be a great "benefit to you and a source of advantage to the "public"?—There is no doubt at all that looked at in that light the matter would seem unjust.

1184. But do you not think it would be unjust?—It would be unjust unless you had a proper compensation for it, but this is the position. Here are towns wanting water—there is no means of supply for them in the localities in which they exist, they have already exhausted their sources of supply, as in the case of Bradford, where you see the reservoirs on the map—they have already exhausted every local supply, and in time they will want more water. Where are they to go to? There is no other place than the Cumberland lakes and that district. And then again there has been an enormous amount of money spent from time to time in those towns in endeavouring to get water in their various localities. Bradford for instance spent some 30,000*l.* or 40,000*l.* in going to Parliament to increase their supply of water.

1185. (*Sir J. Thwaites.*) Has your attention been directed to the question of setting tanks, and to the possibility of precipitating a good deal of mischief which now discharges into Ullswater from the lead mines or the slates?—It has not; but I feel satisfied that the deleterious qualities of lead water cannot be extracted by passing through settling tanks or even by filtration.

1186. You mean that which is held in solution?—Yes, what is held in solution cannot be extracted.

1187. But that which is held in mechanical suspension you can precipitate can you not?—Yes, but with regard to that which is held in solution, there are no means that I know of of extracting that from the water.

1188. Have you had any experience in the filtration of that class of water?—I have not.

1189. (*Col. Harness.*) Have you any idea of the value of the lead mine that is now working at Glenridding?—I have not.

1190. (*Chairman.*) You propose, do you not, to raise the level of the water in Haweswater 30 feet by a dam across the lower end?—Yes, and that would submerge about 273 acres of land in Mardale.

1191. If the whole of the surface of the lake is to be raised 30 feet, how are the sides of the lake to be protected?—The sides are precipitous all round, except at the top part; there is some flat land along the margin of the lake and there are some small cultivated plots at the south end.

1192. In order to give you an additional surface over the whole lake of 30 feet, if the south end of it is flat you would have to raise the north-east end of it a good deal above 30 feet, would you not?—No, in order to get the storage that I require I should raise the north-east end 30 feet and that would submerge about 273 acres of land.

1193. What effect would that have upon the present surface of the lake; how much deeper in fact would the lake be than it is at present?—It would be 30 feet deeper than it is at present.

1194. I understand you that the south end is flat?—It is comparatively so.

1195. (*Sir J. Thwaites.*) On that side of the lake where you see "Haweswater" written on the plan, are you aware that there are farms and houses from one end to the other up to Mardale?—Yes, there are.

1196. It is a small tract of land is it not between the lake and the more mountainous part of the district?—Yes, it is a narrow strip of land.

1197. That would be submerged would it not?—I believe it would.

1198. You would have to purchase that should you not?—Yes, that is included in the 273 acres.

1199. At the Mardale end you would submerge a very large tract of flat land leading up to the Dun Cow inn?—Yes, I think that is the name of the inn.

1200. Have you made any calculation as to the compensation that would be required?—I have put it roughly down under the item of town connexions and works at the lakes.

1201. But you have made no special valuation of the property which will be affected by your scheme?—No, nothing but roughly looking at it.

1202. Have you made any calculation as to the cost of the dam?—Only a rough calculation. I have not made a survey of it nor a cross section.

1203. Have you made no sections?—I have made no cross sections at all of the lakes.

1204. Are the Commission to understand that your estimate is merely a rough estimate?—It is a rough estimate; no estimate can be made but an approximate estimate, unless cross sections and surveys are made and working drawings, the same as if the work was fully gone into. If you have the data on which to base the estimate well and good, but all other estimates are approximate only.

1205. You propose a dam of 30 feet high at the southern end of the lake, surely you can make an estimate of the cost of that dam?—That is included in the other items, but I have not the details as it was not a matured scheme. I did not suppose that I should be asked those details, and I have not them with me.

1206. You propose do you not to take the water from Ullswater round by Clifton and the valley of the Lune?—My proposition is to bring the water first by Clifton and the Cliburn valley

1207. You take your supply from Haweswater and you form a junction south of Clifton?—I do.

1208. And you proceed by an open cutting I presume until you get past King Meaburn to Crosby Ravensworth?—Yes, it is open cutting as far as the trenchwork goes.

1209. Then you have to tunnel, have you not, through Orton Scar?—Yes.

1210. I see that there are alternate lines in your plan at that point, do you propose to carry two tunnels throughout?—No, there are separate schemes. In my first proposal I proposed simply to have one tunnel, the water being brought from both lakes to supply those towns and the tunnel would admit of the water coming from Ullswater, and the tunnel at that level would be some five miles in length; but afterwards in looking at it in order to induce some of the Yorkshire towns alone to take the water and to cheapen the scheme by a shorter tunnel, I proposed to take the whole of the water for the Yorkshire towns from Haweswater alone and to bring it through a shorter tunnel, and the easternmost tunnel is the one which I have marked to show the plan.

1211. Do you know the condition of the rock in Orton Scar?—It is a slatey rock, something like the Welsh rocks at Penmaenmawr and Penmenback.

1212. Have you examined that rock?—I have.

1213. It is a very hard limestone rock, is it not?—It is a very hard rock similar to the rock which was passed through at Penmanback. I was engaged on that tunnel.

1214. What is the length of your tunnel from Crosby Ravensworth to Tebay?—The one for bringing the combined waters of Ullswater and Haweswater would be about five and half miles in length; the other tunnel which is proposed to be made for the waters of Haweswater alone would be three miles in length.

1215. (*Col. Harness.*) Do you keep the pipes separate so as to have the head of the Haweswater water separate?—Yes, there will be a separate head all under pressure.

1216. (*Sir J. Thwaites.*) You take advantage of the elevation of that district?—Yes.

1217. In point of fact you would have two tunnels, or do you propose to bring your pipe through one?—If the Haweswater plan is adopted alone and the Ullswater plan rejected, then I adopt the shorter tunnel, but if both lakes are taken, then the long tunnel of five and half miles would be constructed.

1218. Then those pipes taking the water from Haweswater would be under considerable pressure?—They would if I want to turn the waters of Haweswater upon those towns. I shut off the water from Ullswater by a sluice cock lower down at the junction near Clifton, and I turn on the higher pressure from Haweswater for those towns which are of the highest altitude.

T. Dale, Esq.

21 Feb. 1867.

1219. Then you come out near to the Tebay station?—Yes.

1220. And you then follow the course of the Lancashire and Yorkshire Railway?—Yes, down the valley of the Lune.

1221. (*Chairman.*) What is the size of your pipe?—The pipes vary according to the velocity of the flow and the conditions under which they are placed; they vary from five to seven feet. I may observe that I have furnished also a longitudinal section, showing some of the gradients, but that longitudinal section has been plotted from the contoured lines of the Ordnance sheets, and it is only an approximation. When I first proposed this scheme some 15 years ago, and even since that time, I met with a great many objections and difficulties in getting the scheme before the public in consequence of the continued statements of engineers opposing the scheme, that it was impracticable to carry out the work in consequence of tunnels which would have to be made, some 23 miles in length, and in order to convince the governing bodies of the towns and to meet their objections I drew an approximate section of the surface of the ground as far as Leeds, which is the most difficult part of the ground, with a view to show that the scheme was feasible.

1222. Do you propose to work this tunnel which you state is five and a half miles in length and through very hard limestone from one face or from two faces, or do you propose to sink shafts?—In working that tunnel I propose to sink two shafts, as well as to work it from both faces.

1223. Do you know the depth that you would have to sink those shafts?—No, I have not gone into that, at least I have not the details with me.

1224. Do you know what time it would occupy to drive that tunnel?—The five and a half miles could be driven in from two and a half to three years.

1225. You would depend, would you not, upon the number of faces that you had?—Yes, it would depend upon the number of faces, that is to say, and by sinking down two shafts and working from both ends we should have six different faces to work at.

1226. In all your shafts you would have to blast every inch, would you not?—Yes, every inch would have to be blasted. I have had a great deal of experience in tunnelling. Formerly I was engaged in railways, and I was engaged in the construction of the Penmaenback tunnel in North Wales, which is through a similar description of rock, and I know the number of yards or feet that can be done by the headings of the main tunnels through that description of rock.

1227. (*Chairman.*) Your pipes I think you stated were from five to seven feet in diameter?—Yes.

1228. At this particular point, Tebay, what is the size of your pipe?—According to the flatness of the gradients the pipes increase in size, at Tebay the pipe would be seven feet.

1229. (*Sir J. Thwaites.*) How many pipes do you propose to lay down?—Four lines of pipes, of seven feet. I may state that I propose to take four lines of pipes as far as Leeds, and from Leeds to Bolton three lines of pipes, and from Bolton to Liverpool two lines of pipes.

1230. (*Col. Harness.*) Of those four, how many are from Haweswater and how many from Ullswater?—Haweswater would join on to those four lines at the junction near Clifton.

1231. (*Chairman.*) How many pipes would you take from Ullswater to the point of junction with that which comes from Haweswater?—I should take two pipes from Haweswater and two from Ullswater, they would then become four, and I should go on with four pipes.

1232. (*Sir J. Thwaites.*) What would be the character of the pipe which you would use?—Cast metal pipes, of seven feet diameter.

1233. Would you have them coated at all?—I should coat them with tar internally and externally.

1234. Of what use would the tar be internally?—To preserve the pipes. There are several compositions used for that purpose.

1235. (*Chairman.*) But what would you use?—There is a composition patented by Cochrane, but I should use a composition of gas tar. I would tar the pipes inside and out.

1236. (*Sir J. Thwaites.*) How long do you think the tar would last?—Of course, the waters rushing through from time to time would wash away the tar, but it would last a long time. I should say that it would last some two or three years.

1237. Have you had any experience with regard to that?—I have.

1238. What would be the advantage of having a coating of tar to last three years to pipes placed there for all time?—We put pipes down without any composition at all, but I should put some composition. I am not prepared to say just what, but the best composition I could obtain to preserve the pipes as long as possible.

1239. (*Chairman.*) When the composition wore out, what then?—The pipes must take their chance.

1240. Taking you from the lakes as you proceed onwards I see on the plan that there is a route which proposes the avoiding of a tunnel, is that to avoid this tunnel five and a half miles in length of which you have been speaking?—It should have been put "for the purpose of avoiding the tunnel at Shap Fell," the long tunnel.

1242. (*Sir J. Thwaites.*) You are not going through Shap Fell?—No, I am going round by Kirkby Stephen.

1243. (*Chairman.*) You have told us of a tunnel through limestone rock 5½ miles in length which would take from two to three years to construct; then I see at a place called King Meaburn you have a dotted line which says "route avoiding tunnel;" what tunnel is that?—Avoiding the tunnel through Orton Scar; the Ullswater and Haweswater one of 5½ miles in length.

1244. (*Sir J. Thwaites.*) Have you walked that ground?—No, I have looked it over on the Ordnance sheet.

1245. Do not you know that you would have about three tunnels there by the loop line, if we may so call it?—No; the levels on the Ordnance sheet show that I can bring it round by Kirkby Stephen into the valley at the head of the Lune. If a survey were made there might be a tunnel of some three-quarters of a mile in length, allowing for the gradients.

1246. But through Asby Scar, for example, you would have to tunnel through three times that length?—But that dotted line on the map is just put on approximately. In making a survey perhaps it would go a little nearer towards Appleby coming round by Kirkby Stephen.

1247. By the river Eden you mean?—Yes, nearer to the river Eden.

1248. (*Chairman.*) In fact the dotted line on this plan is not made accurately?—It is approximately accurate.

1249. But if you wished to avoid a tunnel you will have to go somewhere in the direction of Kirkby Stephen?—Yes.

1250. But you have not sufficiently surveyed that country for you to know whether that route would be possible?—I have not, but I am perfectly satisfied that it is possible from the levels on the Ordnance survey.

1251. (*Mr. Harrison.*) You say that you have calculated the size of your pipes according to the gradients, will you just refer to 56 miles on your section?—I may observe that the sizes of the pipes are not calculated according to the gradients on this section. The gradients are generally looked at and the sizes of the pipes determined, but this section was made as an approximate section to show in the first instance that the scheme was feasible as far as Leeds; and I put on these gradients, showing the surface of the ground and the proposed lines of pipes somewhere near the gradients. The sizes of the pipes are estimated approximately, allowing fully for the probable gradients to supply the whole of those towns.

1252. You commence at Ullswater by taking the water at a level of 467 feet, do you not?—Yes.

1253. At 56·67 miles the level of your pipes is shown as being 445 feet?—Yes.

1254. That gives a fall of 22 feet?—Yes.

1255. That gives for 56 miles $4\frac{3}{4}$ inches per mile as the average fall over that distance through your pipes?—Yes.

1256. That, of course, is the basis upon which your calculation will have to be made?—No, in this instance I shall have a greater fall than that. In the calculations which I have made the falls are not less than from 9 inches to a foot per mile; this $4\frac{1}{2}$ inches is only an approximation, and therefore not the fall on which I made my calculations.

1257. Then practically you cannot take this section as being of any use at at all for your purposes?—Not at all; it was merely put as an approximation.

1258. You could with that fall have made it an open conduit of sufficient magnitude to get it to one uniform centre, but surely not through pipes?—No.

1259. Have you at all in contemplation the supplying of any towns further to the eastward, for example York, which is badly supplied?—I have it in contemplation also, and Rotherham and Sheffield also. These waters being brought to Leeds could be trenched off, and the contour levels of the country would admit of these waters even being taken up to York and brought round by Rotherham to Doncaster, Sheffield, and all the towns in that district.

1260. But that is no part of your scheme?—No, my effort has been to attract the attention of the different towns to this source of supply only as a general scheme. I have not been able as a private individual to go further into it. I have spent a great deal of money, some 300*l.* or 400*l.*, in order to induce them to approach it, not as a matured scheme, but only as a feasible scheme.

1261. We may take your idea to be this, that it would be possible by gravitation to convey the waters from Ullswater and Haweswater into the valleys which run down to Leeds?—Yes, by gravitation to supply the different towns, and that it could be done at a reasonable cost.

1262. But you have hardly gone into that question sufficiently?—No. I submit this, that without a proper survey with sections and plans fully matured, no estimate can be made out except approximately for any scheme.

1263. What is the size of the tunnel that you calculate upon at Orton Scar?—For the four large pipes it should be 40 feet in width and 16 feet in height.

1264. (*Mr. Prestwich.*) How many miles of tunnel have you along the whole length of your line?—There are $5\frac{1}{2}$ miles at Orton Scar and some $2\frac{1}{2}$ miles near to Todmorden.

1265. Then you have under 10 miles of tunnel?—Those two would make eight miles.

1266. And what is the total length of the line?—170 miles.

1267. (*Mr. Harrison.*) Do you think that you could make a tunnel of that shape, 40 feet wide and 16 feet high all in one, or would you have to make two?—Yes, it would be better to have it made in two and to have a leg in the centre of the tunnel.

1268. What is your estimate per yard for the cost of that?—I have not the details with me to enable me to answer that question.

1269. (*Chairman.*) I observe that there are 20 towns to which you propose to bring water. In the return which you have given us you state that the highest level at Lancaster is 132 feet; that represents I presume the level which would be necessary to supply all the towns in Lancashire of that level by the Ordnance datum?—Yes, 132 feet is the highest level. Those level were furnished me by the Ordnance department, and I have found since that some portions of the towns are rather higher, and therefore this return would require some little alteration. In Lancashire I show that 20 towns can be supplied with water discharged into reservoirs by gravitation; then I show the highest level in the towns in feet above the Ordnance datum.

1270. You mean that the highest level in the town of Lancaster above Ordnance datum is 132 feet?—Yes.

1271. (*Sir J. Thwaites.*) Take the Castle Hill for example; surely that is more than 132 feet in height?—I wrote to Sir Henry James, and this is the return which I received from him of the highest levels of the towns, giving their bench marks, and I believe they are the highest levels of the towns excepting in one or two instances.

1272. The next column is headed "Head of water, Haweswater, 562 feet," what does that mean?—That is taking the natural level of the lake, say, at 694 feet above the Ordnance datum, there would be 562 feet head of water over the 132 feet, the highest level at Lancaster.

1273. Then "Head of water, Ullswater," you have put down as 345 feet; that is deducting 132 feet from 477 that would give 345 feet?—Yes.

1274. Will you have the goodness to put in that return?—(*The witness delivered in the same.*)

The following towns can be supplied with water discharged into reservoirs by gravitation, as shown by the following table:—

—	Highest Level, Feet.	Head of Water, Haweswater.	Head of Water, Ullswater.
Lancaster	132	562	345
Preston	140	554	337
Wigan	157	537	320
Dewsbury	187	507	290
Wakefield	201	493	276
Liverpool	227	467	250
Leeds	300	394	177
Bingley	278	416	199
Kendal	316	378	161
Bolton	327	367	150
Blackburn	373	321	104
Keighley	388	306	—
Bradford	420	274	—
Huddersfield	429	265	—
Burnley	492	232	—
Rochdale	472	222	—
Halifax	604	90	—
Manchester	—	—	—
Salford	—	—	—
Stockport	—	—	—

1275. (*Colonel Harness.*) When you speak of 150,000,000 gallons, what head are you using and what quantity of discharge?—In going into that matter and determining as to the size of the pipes, I have allowed over and above the size so as to be safe in the estimate, and the altitude of Haweswater being very much above that of Ullswater the velocity in those pipes would differ at different times; sometimes some of the lower towns, for instance Lancaster, would be supplied with water from Ullswater, and the higher levels of towns would be supplied from Haweswater, that being of higher altitude, so as to give a sufficient velocity to the head of water from the two lakes to pass through to the different towns at their various altitudes the quantities of water that they required to make up the 150,000,000 gallons which I have put down as their capacity.

1276. Have you calculated separately for each town what its proper head of water would be and then adopted the aggregate?—Yes, I have.

1277. (*Chairman.*) You have told us that you bring the water by means of two pipes from Haweswater and two pipes from Ullswater, that is four pipes, do you propose to continue to carry it by four pipes the whole way?—I propose to take four pipes to as far as Leeds, a distance of about 90 miles; then three pipes from Leeds to Bolton, a total distance from the lakes of about 145 miles; and from Bolton to Liverpool two lines of pipes, a distance of 170 miles.

1278. And that by iron pipes as you have described the whole way?—Yes, under various pressures, of which I can give some particulars if necessary.

T. Dale, Esq.

21 Feb. 1867.

1279. (*Sir John Thwaites.*) Do you mean various pressures upon the same pipe?—No; I can give the thickness of the rims, the pressure in feet, the weight per yard, and the cost per mile.

1280. (*Chairman.*) I see in one statement you have calculated that you would get a sufficient amount of capital for carrying out the works, will you give us what you consider to be the amount of the cost of the whole scheme?—I put the estimated cost of the works, *viâ* Leeds to Liverpool, including pipes, tunnel, trench works, town connexions, and all other materials and works required to be done, at 11,500,000*l.*, including the whole of this combined scheme. Then Parliamentary expenses and compensations, surveys, engineering, &c., 460,000*l.* in addition, making a total cost of 11,960,000*l.*, or say 12,000,000*l.* in round numbers.

1281. You propose by your statement in this paper to borrow that money by the aid of the Government at four per cent.; what do you mean by that? how are the Government to assist in it?—The Government are to lend the different corporations money at four per cent.

1282. (*Sir John Thwaites.*) How are the Government to raise that money?—I know that in carrying out sewerage works the various corporations have borrowed money from the Government, and money might be advanced in the same way for this purpose.

1283. (*Sir B. Phillips.*) Have they not rather borrowed them from public bodies under Acts of Parliament?—I think that that has been the way in which the money has been raised, and this is the idea that has occurred to me.

1284. (*Chairman.*) How long do you propose that those works should take in construction?—I should say that this combined scheme would take six years.

1285. (*Mr. Harrison.*) What have you added to the 12,000,000*l.* for the accruing interest during the construction of the works?—I have put nothing down for that; I have put down in the yearly expenditure interest at 4 per cent. upon that amount.

1286. What does that come to?—478,400*l.*

1287. Up to the time when you complete your works, the accruing interest during that period on your borrowed money would form a part of your capital?—It would.

1288. In addition, whatever it may be, to the 12,000,000*l.*?—It would.

1289. You would not borrow all the money at once, but if you take six years for construction, there would be the interest, say for three years, at 480,000*l.*, or in round numbers 1,500,000*l.* which would have to be added to this 12,000,000*l.* for accruing interest?—Yes, that would be so.

1290. That would make it 13,500,000*l.*?—Yes, that would be so, taking that view of it.

1291. (*Chairman.*) Have you made any calculation what the annual cost of keeping up those works would be?—Roughly I have done so. I provide also a sinking fund of 3 per cent. amounting to 358,800*l.*; that fund would be a sort of renewal of works fund, or to pay back the total amount of the cost of construction in a given number of years.

1292. (*Sir John Thwaites.*) What number of years do you calculate?—I calculate about 25 years at 3 per cent., but I have not worked that out.

1293. (*Chairman.*) The whole of this scheme is to be a supply by gravitation, is it not?—Yes, the towns are all to be supplied by gravitation.

1294. But in consequence of the immense expense which would fall upon any individual to make anything like an accurate survey of the country through which these works are to pass, your scheme deals rather in generalities and not much in details; it is more a general scheme which you have drawn up for the benefit of the corporations of those towns, in order to show them that instead of laying out their money in attempting to get water from the districts near to the towns which you have mentioned, it would be possible to bring water from Ullswater and Haweswater by means of iron pipes through the district which you have described, but that you are not prepared to go into any details of sections or levels as to how you would bring it?—I am not able to do so, because it is beyond my power and pecuniary means to do so.

1295. But the object that you have in view is to call the attention of the corporations of those different towns, to what in your opinion might be done for them to amend their present supply of water?—That has been my object.

1296. But yours is a very general scheme, and therefore must not be taken as anything like one that is perfect or fit to be criticized in detail?—Of course not; it is not a fully matured scheme, but this I have to say that I am fully convinced, so far as I have been able to go, that the works could be carried out for less money than I have put down.

1297. (*Mr. Prestwich.*) Many of those towns which you propose to supply with water are already supplied by collecting grounds on the millstone grit which you have told us is a good collecting ground; nevertheless, you consider it would be advantageous to substitute for such gathering grounds the gathering grounds of the lake district which you now suggest?—I do.

1298. Is there reason to believe that there is cause to object to the water supplied by those gathering grounds to those different towns?—I have received letters from some of them this morning, stating that the whole of the towns which I have mentioned are short in the quantity of water, that the waters are impure, and that when they have to apply to Parliament they meet with opposition from millowners and landowners, and that the sums of money that are spent are immense; and my object is, and what I wish to impress upon the Government is this, that they shall say to the people of the different towns the mountainous regions are the proper gathering grounds, and you shall have those gathering grounds; we will allow no more reservoirs to be constructed in valleys causing insecurity to property and deteriorating the value of the land that ought to be appropriated to manufacturing purposes and to agricultural purposes, but these are the gathering grounds that you shall go to and save all this amount of money. I also propose that there shall be an executive in London and a president of a water board appointed, who shall have control over the local directors the same as the general board in London has in the case of the poor law, and that those directors shall be representatives of various towns according to the rateable value of those towns, and that they shall sit at that board, but that their doings shall be under the control and sanction of the executive government. At the present time in obtaining quantities of water for towns the local representatives are generally men whose popularity rests upon their reducing the rates, and when they go for a scheme they go for the cheapest scheme that they possibly can without looking at the ultimate benefits to be derived from providing pure water for the population.

1299. (*Sir J. Thwaites.*) You are an officer of a municipality, are you not?—Yes, I am.

1300. Then you have not faith in municipal government?—I am speaking now with respect to what I consider false economy in providing water for various towns.

1301. Do not you think it right that municipalities shall spend as they please their own money?—Still there ought to be a controlling influence over them to see that their money is spent properly, especially where the health of the different populations is brought to bear, as is the case in Hull. I may say that we are cholera proof there; and I have some statistics, which I could produce if it were desired, as to the use of spring water and river water there.

1302. (*Mr. Harrison.*) Have you any special returns with regard to the Hull water?—In Hull we have had river water supplied to the town, and in the year 1849 there were some 2,000 deaths from cholera. Now, we have had spring water introduced from the chalk by an artesian well, which is yielding at the present time about 5,000,000 gallons of water per day, and during the last visitation of cholera last year we

had no cases, excepting about four which had been imported, and the people of Hull escaped.

1303. (*Chairman.*) I presume we may conclude that Hull is a great deal better drained now than it used to be?—It is undergoing drainage at the present time, and certainly that has to be considered as well, but bad water, I believe, is a great incentive to cholera.

1304. (*Mr. Harrison.*) If I recollect rightly, it was the sinking of a little well by the railway company to get water for their locomotive engines which induced the corporation to put down wells in the chalk?—The corporation of Hull have been for centuries in possession of natural springs at Springhead, near Hull, which formerly had supplied the town with water, but which had been disused, when the wants of a largely increased population required a much larger supply than they could yield. In consequence of which, about 25 years ago, recourse was had to the fresh water of the navigable river Hull; but this proving impure, about six years ago extensive works, with artesian bores of large diameter, were constructed on the site of the old wells at Springhead, at a great cost, from which a most abundant supply of pure spring water was had for the use of the town.

T. Dale, Esq.
21 Feb. 1867.

1305. The corporation charged so high for the very bad water which they supplied that the company put down a well in the chalk to supply water for their own engines?—Yes.

The witness withdrew.

Adjourned to Wednesday, the 6th of March, at 2 o'clock.

Wednesday, 6th March 1867.

PRESENT:

HIS GRACE THE DUKE OF RICHMOND, K.G., IN THE CHAIR.

Sir JOHN THWAITES.	Colonel HARNESS.
Alderman Sir BENJAMIN PHILLIPS.	THOMAS ELLIOT HARRISON, Esq.

JOSEPH PRESTWICH, Esq.

ROBERT RAWLINSON, Esq., examined.

R. Rawlinson, Esq.
6 March 1867.

1306. (*Chairman.*) You are a Companion of the Bath, a Civil Engineer, and a Fellow of the Geological Society?—Yes.

1307. And you are officially engaged as principal inspector to the Local Government Act Office?—Yes.

1308. And you were government engineer to the Lancashire Board of Public Works in 1863 and 1864 during the cotton famine?—Yes, and I remain so; the works are not completed.

1309. And you are chairman of the Royal Commission which is now sitting to inquire into the pollution of rivers in England and Wales?—Yes.

1310. And a member of the Army Sanitary Commission at the War Office?—I am.

1311. You have been generally engaged in civil engineering since 1831?—Yes.

1312. Were you engaged on the London and Birmingham Railway?—Yes, I was for four years under the late Mr. Robert Stephenson.

1313. You were inspector under the First Board of Health?—Yes.

1314. Were you the Sanitary Commissioner sent out by the government to the army in the Crimea?—Yes.

1315. Where you were wounded, I believe?—Yes, I was.

1316. Have you generally given much attention to the subject of water supply?—Necessarily so. I have examined officially the reservoirs of Lancashire and Yorkshire for the Home Office since the bursting of the Dale Dyke Embankment, and have reported upon them.

1317. Have you also examined the Valley of the Thames?—Necessarily so, as chairman of the Rivers Pollution Commission I have, in conjunction with my brother commissioners, examined the main valley of the Thames and have reported to Parliament. The Thames Conservancy Act has been passed since, and is now in force.

1318. Did you report in the year 1846 on the proposed supply of water from Bala Lake, in North Wales, to Liverpool and other towns in Cheshire and Lancashire?—I did. I hold a copy of the report in my hand.

1319. Will you have the goodness to hand in that report?—Yes. (*The witness delivered in the same.*)

1320. Have you been engaged in the construction of impounding reservoirs?—I have. I am just completing an impounding reservoirs now for Swansea.

1321. And have you inspected impounding reservoirs in Lancashire, Yorkshire, Wales, and Ireland?—I have.

1322. Have you inspected the lake districts of Cumberland, parts of Scotland and parts of North Wales?—Yes.

1323. Have you carefully considered the natural features in mountainous districts, favourable and unfavourable for the formation of water works?—Yes, I have. There are many peculiar features in mountain districts which require an engineer to have some practical knowledge to know what form of bank should be put there, and what precautions should be taken to ensure its safety when there. I can quite imagine that natural features may present themselves which a person who had not had actual experience in reservoir making might think most desirable, but which if not duly considered might prove most disastrous if reservoirs are made.

1324. Have you also considered the geological characteristics of the several strata as favourable and also as unfavourable to the formation of impounding reservoirs?—Yes; the geology of a district requires to be very carefully considered and to be well understood in proposing to make large impounding reservoirs in fact artificial lakes; it would be a very risky thing to propose to make large impounding reservoirs, of very great capacity in the mountain limestone district for instance. There are many portions of the oolites where it would require very great care, and there are some geological characteristics which an unskilled engineer might imagine very favourable, but which, if he did not know what the ultimate consequences might be, would be very unfavourable. For instance, it might be considered a very favourable feature to have a valley where the subsoil was clay, and an engineer might think that he was very fortunate in having a clay subsoil upon which to form his embankment; but if he placed his embankment and his outlet works upon such clay subsoil without making proper arrangements for what might take place, that is to say, subsidence on compression, when he had nearly completed his work, he might find that he had spent his labour for

R. Rawlinson, Esq.

6 March 1867.

nothing. I have seen embankments made in such districts which have gone completely to ruin, and I have seen outlet works utterly destroyed. Again it is a very natural thing to imagine that clay would be about the best possible thing from which to make an embankment. Now the clays and marls of the oolites are most treacherous and about the worst possible thing an engineer could have to make embankments with. The clays of the lias will dig out apparently as sound as cheese, come out in big square lumps, but if put into an embankment and wet weather gets to them they will melt into the consistency of cream, and I have seen embankments where such clay has been used that would not lie at 7 to 1, they have melted like cream and run out at the foot and utterly ruined the work of the engineer. These are features which to experienced men of course are very well known, and to them I may seem to be talking nonsense; but to non-experienced men it is of the utmost importance that this knowledge of them should exist.

1325. (*Mr. Prestich.*) What is your reason for objecting to the mountain limestone or to the oolites?—First of all mountain limestone has been acted upon from the earliest time at which it has been exposed by the pure water raining down upon it and taking up the lime, that is to say, every million gallons of rain-water falling upon that limestone would take away about a ton of bicarbonate of lime, and carry it away, and it takes it away not uniformly over the whole area but from fissures. There are mountain limestones fissured from the surface to unknown depths in some instances. Take the case of Ireland, where there is an enormous amount of mountain limestone, and where lakes and large rivers lose themselves; there are lakes with no visible outlet but which have their outlet through the fissures of the limestone. For example, in the case of the two lakes at Galway, the upper lake empties itself into the lower lake in dry weather through the fissures; extreme floods do fill it up, and then the water goes over the surface. There are rivers in Galway which are swallowed up by swallow-holes: of course the water is not lost, it comes out again somewhere. Therefore if you attempted to make impounding reservoirs in mountain limestone you might have the surface space covered with vegetation hiding the fissures, so that an engineer might be at all the trouble of embanking a reservoir which would not hold water when it was made. The millstone grit is the same if injudiciously bared. In the case of one reservoir at Liverpool, known as the millstone embankment, the embankment was made from the inside of the reservoir; a large quarry was opened inside the reservoir space, but the water broke away through the fissures and got down through the sub-strata. I saw about a quarter of a mile below the embankment. I think it was something like 3,000,000 gallons of water had burst up in the middle of a field, and I understood that they had then spent 8,000*l.* or 10,000*l.* in trying to stop the leak, but never learned that they did stop it.

1326. (*Chairman.*) Have you considered at all the mode of supplying London from any of the high districts of the country?—I have not—that is to say, other than that I have read Mr. Bateman's pamphlet, and I have read the pamphlet of Mr. Hemans and Mr. Hassard, and I have read Mr. Dales's pamphlet, but before reading them I had not considered the question.

1327. Since reading them what conclusions have you arrived at as to the feasibility of bringing water from either district or both districts to London; in the first place, as to the feasibility of it setting aside the expense?—I have no doubt at all as to the feasibility. I think either Mr. Bateman's or Mr. Hassard's scheme could be carried out if expense is not a consideration, and most unquestionably I believe the volume of water which they propose to obtain and bring could be so obtained and brought, and of the quality which they indicate—that is to say, of a soft and pure quality. I do not know what Mr. Bateman wants with a conduit having 12 inches of fall to the mile, which I see he proposes to make. If he attempts to make a conduit having a surface grade of 12 inches to the mile, I am perfectly sure he cannot work it.

1328. (*Mr. Harrison.*) The average fall between where he proposes to take the water and London would be about 11 inches, but in the actual construction of his conduit I think the maximum which he allows at some particular places in tunnel is seven inches?—In tunnelling he may give what fall he likes, but in an open conduit of the magnitude which he contemplates I am perfectly certain he must give no such fall as 12 inches per mile.

1329. (*Sir J. Thwaites.*) You mean that it is too much?—Yes, the river Lee, with a very much less conduit than is proposed, has a fall of six inches per mile, but that is modified by stop gates and weirs. It is broken into vertical falls in fact. When you have a conduit above a certain size, when you begin to deal with water in millions of gallons, as in a canal (for it would be a huge canal, of course) an engineer would very soon find that he would get such a scouring velocity that he would have to modify it and put stop gates. I do not object to 12 inches. I believe that it would be a great advantage to have that amount of fall, but the water would have to go over vertical falls.

1330. The maximum fall which he proposes in any of his open conduits is six inches per mile?—Yes, and he would have to modify that by putting in stop gates. He could not run a conduit of that size with a surface grade of six inches per mile, it would cut his work to pieces.

1331. You are aware, are you not, that he proposes to line the whole of it from end to end?—If you get 2,000,000 or 3,000,000, or 5,000,000 or 6,000,000 gallons of water per day, you may have a conduit with a fall of five feet per mile, but as you get a larger volume you must lessen your grade. The Bridgewater canal has a velocity of $1\frac{1}{4}$ miles per hour, with only a surface fall given to it by drawing the locks at Runcorn.

1332. In that case they have merely the natural surface of the ground that it runs over?—Yes, the Bridgewater canal, which was laid out by Bentley, contours the country. Of course all canals are on the surface level, and any velocity that they have is the draught of the locks.

1333. The whole of it is not lined, I believe?—No, it is merely puddled—nor is the Lee.

1334. But Mr. Bateman, where he proposes to give six inches fall to the mile, proposes to line it entirely?—I am quite sure Mr. Bateman would have to put in stop gates. I do not say that that disparages his plan at all; I believe it would be better for it. I would rather have a vertical fall. I think it is a very providential thing that water will only work that way. I think it would aërate the water very much.

1335. (*Chairman.*) I gather from you that you think either scheme is quite feasible?—Most unquestionably, if money is not taken into consideration.

1336. I am speaking now, first of all as to the capability of the country, in either Wales or the Lakes district, to furnish the supply of water that is required?—I think that Mr. Bateman's area of country and the reservoirs which he has proposed would give the volumes which he has relied upon. He has had so very large an experience in collecting and storing and distributing water, that if I had no experience of my own, I should be inclined to rely upon his evidence; but I have had experience which corroborates his.

1337. You have not probably had any experience in that Welsh district as to the rainfall?—No; that is to say, I cannot give you actual gaugings, but still I believe that he is not far wrong there.

1338. How do you arrive at that conclusion?—In those mountainous countries, the countries on the west and south of England, of course the rainfall varies for every square mile, but I believe the average would be from 50 to 60 inches per annum; but then averages are not to be relied upon. You must not take averages,

you must take minimums, and that Mr. Bateman knows as well as I do.

1339. (*Mr. Harrison.*) I presume when you reported on Bala Lake you had your attention a good deal directed to the rainfall there?—Just so; and then I have returns every month from Swansea. I have a record of the daily rain gauge for the last six or seven years; the depth amounts to from 50 to 60 inches, and it is rather dry there. Mr. Bateman would have more rainfall than we should have at Swansea.

1340. (*Chairman.*) From your experience in that district you would have no doubt that Mr. Bateman's calculations are correct as to the quantity of water which he anticipates being able to obtain in that district?—I believe he would not have any difficulty. The questions as to storing it, and the advisability of storing by artificial means so large a volume, and the cost of storing it, are other questions, but his calculations as to the volume available I think may be relied upon, and as to the quality also.

1341. (*Mr. Harrison.*) Do you think that the 12 inches which Mr. Bateman calculates for waste would be sufficient for that particular district?—Yes, I think so.

1342. In fact, you have lately had your attention a great deal directed to the subject of what is available, as I judge from reading your report?—Yes, but your brother has gone far more fully into that question with regard to the Thames than I have, and I think he could give this commission some very interesting information. He has worked out from gaugings the actual rainfalls from the whole valley of the Thames, and he can give you more interesting information than any person I know, because he has thrown the information into diagrams.

1343. (*Chairman.*) I presume you have taken the quality of the water which he proposes to supply from Mr. Bateman's own statement?—Yes, and from my knowledge of the geology of the district. At Swansea the water is below four degrees of hardness, and that comes from sandstones in the coal stratification, in fact, it is part of the coal measures, and they are not calculated to give water so pure as the granites and clay slates, which Mr. Bateman's district is.

1344. What is the quality of the water in the lake district?—That is just the same—very soft.

1345. (*Sir B. Phillips.*) Have you turned your attention to the economy of using soft water as compared with hard?—Yes, necessarily. I was one of the inspectors under the Board of Health when their great report was written, and they had all the analysis before them, and I have fully considered the subject of economy in its use in every way.

1346. (*Chairman.*) Do you corroborate what Mr. Bateman states to the Commission that there is very great economy in household purposes and manufacture in the use of soft water over hard?—I have no hesitation in saying that Londoners could have tea of the same strength they are now drinking at half the expenditure of tea if they had water of the same quality as is supplied to Manchester as compared with the Thames water. They would save also in soap, and in the washing of linen, as also washing of clothes of all kinds, they would save directly in the less consumption of soap, and they would save indirectly in the less wear of the clothing, they would want less rubbing, they would save in labour in fact, and then for all steam purposes you get steam much better with soft water than you do with hard water. The amount of fuel is not perhaps an item which one would take much note of, but all users of steam power would pay more for soft water than they would for hard water, it does not foul the boilers. In the case of locomotives on the northern lines, as they go through Lancaster the Lancaster people supply them with water from the millstone grit, and there is something like 1,000*l.* a year paid in that little town by railway companies for supplying them with soft water, and it serves to cleanse the boilers or free them from sediment which they have got in the hard water district.

1347. The quality of the water being the same in the two cases, both the lake district and Wales, the result of course would be the same?—Yes.

1348. Mr. Bateman proposes to have large reservoirs but you seem to throw doubt upon the propriety of large reservoirs?—If the element of money is not to come into the field and consequently a few miles of distance would not be thought much of, I certainly should give the preference to that scheme which availed itself of natural lakes to the largest extent, and which did not require impounding rather than to one which trusted entirely for so large a daily volume of water to the system of artificial impounding.

1349. What is the objection that you would have to artificial impounding as proposed by Mr. Bateman?—There is always the risk that you have to contend against the elements, and if the works are not made with the most extreme care and much more costly, than any reservoirs which I have seen in my inspections, they will not stand. I believe that we have made mistakes in our modern engineering in reservoir embankment making, proprietors, companies, and local boards want the work to be done cheaply; but I hold that it is absolutely impossible to make a cheap embankment, that is, it is impossible to make a reservoir embankment at the same rate of cost at which railway embankments are made, and yet if you have to deal with local boards, they do not want to pay any more.

1350. Have you inspected the mode in which Mr. Bateman proposes to build these reservoirs?—That is a matter of detail to which he has given no key in his scheme, it is a matter for the future. I have seen some of Mr. Bateman's reservoirs in progress and some of the embankments which he is making—and I can only say in his presence that I should spend more money upon them than he is doing. If I were going to follow my profession as a reservoir maker, I should never sleep easy in my bed, if I did not watch most carefully every foot of the bank as it rose. Those reservoirs at Sheffield were very badly made.

1351. (*Sir B. Phillips.*) In other words you think that there is greater security in a natural than in an artificial reservoir?—Yes. The Hindoos have a forcible expression with regard to an arch, they say it never sleeps. That is absolutely true as regards water, for if you put water under pressure it never sleeps, it is everlastingly searching out the weakest point in the reservoir. For instance, look at the Dublin Reservoir, there never was a better bank put together. I saw it when they were making it, and I know that it was put most carefully together, but the water found out the weak point. I have not been there since the leakage has taken place, but I was there when the culvert was being made, and I remonstrated with the engineer. I begged of him not to make it of hewn ashlar, he thought that he was doing right, as I daresay nine out of 10 engineers would think, in making it of hewn granite ashlar; many engineers would infer that hewn granite ashlar was the best thing to use; but I am speaking in the presence of Mr. Harrison, who knows perhaps better than I do that in the case of ashlar of any kind if it has to resist water under pressure, the beds and joints are the weakest parts in the masonry, especially where there is the slightest liability to motion. I would either have made that outlet culvert of brick or rubble, I would have made that culvert of rubble if it had been my work, put together with one-third mortar. Mr. Hartley, the greatest dock engineer, I think all engineers will allow, as far as my reading goes, that any age has produced—certainly the greatest in modern times—began executing his docks of ashlar, hewn in such a manner as I believe stone was never hewn before since the world stood, so rigid and so careful was he. It would be too long a story to tell you how it was done, but that was the weakest work that he put together, and during the later years of his life for dock walls, and for river walls, and all the work he did, he used granite rubble. At the great granite quarries in Scotland from which the ashlar had been produced were mountains of what we term scablins, the pieces which are knocked off by the hammer and thrown to waste, those were brought up by ship

R. Rawlinson, Esq.

6 March 1867.

to Liverpool; and his dock walls, his river walls, his fence walls, and everything, were built of rubble. In fact he migrated from the fine hewn ashlar to rubble.

1352. (*Mr. Harrison.*) I do not understand that you at all assume that the banks proposed by Mr. Bateman could not be made in the particular cases he proposes?—No; I only assume that he must put more money in them than it has been customary to put into embankments previously, as far as I know of them, and very probably his great experience would lead him to do so.

1353. (*Chairman.*) What I gather from you is that you would have no objection whatever to a reservoir such as Mr. Bateman proposes, provided that it was properly made?—No; I think you may do as has been done in India, where there are embankments 3,000 years old, upon a scale larger than anything hat Mr. Bateman has projected, and with monsoon rains as heavy as anything we have here.

1354. (*Mr. Harrison.*) You are merely referring to these matters as showing that reservoirs require perhaps the most caution of any engineering works which are constructed in the present day?—Yes; as this evidence may be looked at hereafter, I am merely putting on record my expression of opinion that reservoir embankments cannot be made at the same rate of cost at which railway embankments are made; you cannot tip with waggons.

1355. These embankments which are proposed by Mr. Bateman, in point of fact would not be larger, would they, than some which have already been constructed in England?—No. The test of an embankment is its vertical depth, it is not its length, or anything of that kind, it is its vertical depth.

1356. We may take it, may we not, to be 80 feet depth?—There are plenty of reservoir embankments of that height, and I think that Mr. Bateman has made some himself 120 feet.

1357. I think that all engineers got a little warning from the failure of that Sheffield reservoir, and I think since that time we may assume that they will take a great deal of care in ascertaining by borings and otherwise the exact nature of the stratification before they commence to put a reservoir upon any particular place; and if all those precautions are taken, is there anything within your knowledge that would lead you to say that what Mr. Bateman proposes is a work beyond ordinary embankments for reservoirs which have been made in England?—No; I believe that those embankments which he proposes to make may be made, and that they would endure any amount of wear, and last as long as time itself.

1358. Your suggestion is that every one of those precautions should be taken primarily before the work is begun?—Yes. The Commissioners must not imagine that I am speaking thus in disparagement of Mr. Bateman's engineering skill. I am only putting on record my opinion as to how embankments have been made, and that some amendment is required for the future. When I use the word "amendment" I mean that an engineer must be backed up in incurring extra expenses; that he must not be ground down in his estimate. It is a most fatal thing to any company having to deal with embankment works, to want what they call a cheap job.

1359. As a result of your examination lately as chairman of the Rivers Pollution Commission, do you think that even the carrying out of the suggestions which you have made in your report on the Thames, will purify the water of the Thames so as to make it a desirable drinking water?—If you mean by that to ask me whether the Companies now pumping direct from the main Thames continuing to pump from the direct main Thames would get pure water I say No.

1360. Is it not quite clear that in order to avoid supplying impure water they must incur before long a considerable additional cost?—Necessarily in my opinion, I think that they could get water from the Thames for the London of the present, and for the London of the future, and that they might get it as pure as the stratification will admit of, but that it will never be such water as North Wales would give them, that is to say, it would always be water impregnated with lime to the extent of 14, 15, or 16 grains to the gallon which it is at present. If you took it from its spring sources, or if you took it from its gravelly subsoil on the margin of the main stream, you might get it without its mechanical impurities; but it would have its chemical impurity if you would call it impurity; you would still have the lime which is now in combination with the water.

1361. Had not Professor Way analyzed a great number of waters for your Commission during your sittings in various parts of the country?—Yes, he is analysing now all the waters from the Aire and Calder valley, and he is going out on Friday and Saturday to collect samples from the river Lee valley.

1362. I presume he will have formed a pretty good conclusion from all his experience as one of the members of your commission as to what is the best quality of water generally speaking for a large population?—He can inform this Commission as to the salts and mineral matters combined in waters. The economy and wholesomeness of water form parts of other questions.

1363. Is that a point which you have had to go into in your inquiries?—Not upon the Pollution of Rivers Commission. I had to go into it as an inspector of the first Board of Health when their first water report was published: it was then a duty imposed upon me to go into the question.

1364. And what was the result of your inquiries then?—The result was that we always recommended soft water to be sought for, and additional expense to be incurred to secure soft water in preference to hard water, for the purposes of domestic use, and as being more wholesome to drink.

1365. (*Mr. Prestwich.*) Have you paid attention to that particular subject as to which is the best water for health?—Excepting this that I find very curious and very conflicting evidence; but I believe it all wants qualification. You have populations living in soft water districts, and drinking soft water, and not only suffering no injury, but I believe gaining advantage by it; but if you removed a person from a hard water district to a soft water district, or *vicê versâ*, there is a great risk of your upsetting the economy of his system, and making him ill for a time. Sporting men understand it so thoroughly, that no man owning racehorses or training racehorses would dream of changing the water, whatever it be, that a horse has been trained upon, in the interval between the training and its race. If a groom gave a horse hard water that had been trained upon soft water, he would make it what a jockey or a groom knows as "penny;" his coat would stand up, and the horse would be out of condition. I believe that human beings are acted upon in the same way.

1366. (*Chairman.*) Must you not qualify that opinion, because it is not the practice, is it, to carry water about with horses?—Then I have been misinformed.

1367. For instance, if the horse is trained in Sussex and he runs at Doncaster, is water taken with him?—He has his water sent down in some cases. Of course your Grace knows a great deal better about these things than I do. I know that when the celebrated horse "Birmingham" won the St. Ledger he came from Birmingham, and (by repute) his water was sent up for him.

1368. Possibly that arises from the fear that somebody may what is called in the language of the turf "have got at his water" the place where he was going to?—That may be so, but I know that hard water will set a horse's coat wrong and make him what a groom would call penny. If you let him drink very hard water you would affect his skin directly. I know that soft water is preferred to train horses upon. The stables down in Yorkshire are upon the oolitic district, and there are some racing stables about Salisbury, and all the water is caught

on the slated roofs and taken down into cement tanks for the drinking of the horses.

1369. (*Mr. Prestwich.*) Is that on account of the water being so hard or on account of the deficiency of water?—No, it is on account of the softness of the rain water; there is never any deficiency of water in the oolites, you can get abundance of hard water.

1370. Do you know what the soil is in the neighbourhood of Salisbury?—They have plenty of chalk water there, but they catch the roof water for the horses. I think there are some training stables near St. Giles's and they catch their roof water there and take it into tanks. When I wrote the report which I have handed in I read up the literature of water to a very great extent, both what prose writers have said, and what poets have said about it, and there is this fact with regard to hard and soft water. All soft water districts have a race of people much healthier, better looking, with fresher complexions than the people living in the hard water districts. It is very curious that all the crêtenism and goitres of the mountain districts are located upon the limestone in the Alpine district; the Alps are oolitic generally.

1371. Do you say that the people are more healthy in soft water districts?—Yes, they have fresh complexions, and that has been remarked in all ages and by all writers. The old poets of the East sing of the sweet waters and the Circassian poets also. The Circassian valleys from the clay slates and granites produce soft water. In all the fresh water districts, the Bala district and the valley of the Dee, the girls are noted for the freshness of their complexion and their personal beauty.

1372. What is the quality of the water in the Highlands of Scotland?—It is soft. It is from the granites and clay slates. And with regard to the unwholesomeness or risk of changing from hard water to soft or changing the water generally when the Duke of Cumberland went into the Highlands after 1745 his entire army was disorganized by drinking the lake waters which brought on diarrhœa and spasms. Sir John Pringle records these facts in his journal, and I can quite understand it. I have been twice in the Highlands of Scotland and having read up this question of soft water, and being so thoroughly imbued with the idea that soft water must be beneficial, I took to drinking a tumbler before breakfast and it brought on spasms. I did that twice with the same result, and I have no doubt at all that the soft water possessing more of the property of a solvent, acted upon the gastric juices and put me in a condition which I found very undesirable.

1373. Do you think the water which is used in Scotland is very wholesome water?—It is wholesome for the people who live in Scotland, but as I say before one was acclamatized to it it would be risky for any person to drink the water without proper precaution. That question of water drinking is not sufficiently paid attention to by our physicians. There is not a favourite sea bathing or summer place on the coast of England on the east or the south which does not give you very hard water, and if very delicate people are sent down to Scarborough the water is hard. It is hard at Brighton, and it is hard at all those places on that coast.

1374. (*Mr. Harrison.*) Taking it as a whole after they get acclimatized to soft water, if we may use the expression, the result of your information and experience is that the soft water is decidedly the best?—I think so; all the evidence is in that direction. For instance, it seems to be more wholesome, at least I am told that persons who pay attention to the breeding of stock and especially of horses prefer soft water. I think that all animals themselves prefer soft water to drink. You will find that horses and cows will go to a dirty ditch rather than go to a bright spring.

1375. (*Sir B. Phillips.*) According to your theory, having lived in London, you think that people having been accustomed to hard water if you were to bring in a supply of pure soft water, would for a considerable time until they became used to it necessarily suffer in health?—In the masses of the people you would have a per-centage that it would effect, but we unfortunately do not drink so much water as we ought, any of us.

1376. (*Mr. Harrison.*) Out of 30 gallons, taking it at 30, which is supposed to be consumed per head in London, what proportion do you suppose is actually used for drinking?—I should think that if you take London all over you would not have one half a pint per day of water drunk per head. I profess to be a water drinker simply because nature will not let me drink anything else, but then I am also a tea drinker: I do not perhaps drink half a tumbler of water in a day, and yet I cannot drink beer.

1377. (*Mr. Prestwich.*) I suppose that nineteen-twentieths of the water used for drinking in England is hard water?—I think it would be so, that is if you take nine or ten degrees as hard water, and we say that all above six degrees would come into the list of hard waters, and that all below six degrees you would call soft waters—that is six grains of lime, or bi-carbonate of lime, to the gallon.

1378. May not the observation which you made just now with regard to the better health of people in districts where soft water is used arise from the circumstance that almost always when you get into a mountainous district, you get into a granite or a slate district where the water is necessarily soft, and also as we know that in mountainous districts the air is generally pure, may not the better health arise from the purity of the air as well as from the softness of the water?—Yes, that may be so where the water is soft and pure, but you have a most degraded type of human life in mountainous districts also. I do not know that you can show in soft water districts anything analogous to the crêtinism and idiotcy which are to be met with in the hard-water valleys and mountain ranges of Switzerland.

1379. Has that not also been ascribed to the confined air of the valleys and other causes?—I think it is the result of a combination of causes. I think it may be due to the miserable and wretched way in which they house themselves, and very probably to the bad and innutritious food which they are brought up upon owing to the poverty which exists there, but as far as I am aware you never find the same amount of disease in a pure water district.

1380. But the water in the valleys where crêtinism prevails differs so very greatly—in some places the water is soft and in other cases it is hard—and I believe that the theory which ascribes crêtinism to the quality of the water has been given up because in many cases the water used is merely melted snow water?—That possibly may be the case.

1381. (*Sir J. Thwaites.*) You have prepared a plan for supplying Liverpool with water, have you not?—Yes; the plan which is described in the report which I have handed in, and which was prepared 20 years ago, in 1846, was to take in water from the valley of the Dee, which has Bala Lake at its head, and that is essentially soft water.

1382. Have your views altered at all as to the capacity of that lake to supply Liverpool?—No; if you look at this report you will see that I proposed to make a conduit commencing 30 or 40 miles below the lake, and to have made the lake into an impounding reservoir on a plan similar to that which Mr. Bateman has adopted in his great Glasgow works.

1383. That part coloured blue in your map, which is gathering ground, comprises an area of 289 square miles?—Yes.

1384. And that coloured dark blue an area of 38 square miles?—Yes.

1385. Do you propose to utilize this lake as a reservoir?—I did; I suggested that.

1386. Has subsequent reflection caused you to alter your previous view?—No. I do not know what has been done on the margin of the lake; I have seen a map with a railway carried alongside of it, but there was no such railway when I was there 20 years ago.

R. Rawlinson, Esq.

6 March 1867.

1387. That would prevent, would it not, your raising the level of the surface of the lake?—No, because I should propose to shift the railway higher up.

1388. Did you propose to raise the surface level?—Yes; I proposed to raise it 6 feet, and drive a heading and draw off 12 feet, and I should take power to draw it 12 feet below the ordinary level and to raise it 6 feet above.

1389. Are there any houses surrounding this lake?—There were not at that time.

1390. What is the utmost quantity of water that you hoped to obtain from this source?—I proposed in 1846, I think, to have given them works for 30,000,000 gallons, but all the permanent portion was capable of going up to 60,000,000 gallons per day.

1391. Is that the maximum?—No; the volume of water passing through the bridge at Llangollen is at least 550,000,000 gallons per day; the average quantity, taking 365 days, the minimum dry weather flow is about 60,000,000 gallons.

1392. You separate the 38 square miles, do you regard that as auxiliary?—Yes; there is a mountain ridge, what is called the Berwyn mountains, 2,000 feet high, between the two areas.

1393. Can you tell us the amount of rainfall on this district, the area of which is 289 square miles?—It varies from about 40 to 80 inches per annum.

1394. What is the average?—About 60.

1395. What deduction from the average of 60 inches have you made for absorption and evaporation?—The area is so enormous and so much beyond what the requirements of all Lancashire could be that I never troubled myself about that.

1396. Did you gauge the water near to the bridge at Llangollen?—There is a weir to supply the Ellesmere canal at a place called Llantysilio, about three miles above Llangollen, and I gauged it there several times. There is a conduit which carries the water across the Pont-y-cysslte aqueduct, taking 20,000,000 gallons per day for the supply of the Ellesmere canal; I gauged it frequently at that weir, which was made by Mr. Telford.

1397. (*Col. Harness.*) Then the quantity passing under Llangollen Bridge is what flows down after that is taken away?—Yes; they take 20,000,000 gallons regularly for the supply of the canal.

1398. (*Sir J. Thwaites.*) What quantity in the average of an ordinary year's rainfall passes under that bridge after the abstraction of 20,000,000 gallons?—About 550,000,000 gallons per day in round numbers.

1399. Do you state in your pamphlet what height this is above the ordnance datum?—It is 330 and some odd feet at the point Llantysilio.

1400. The lake is higher than that, is it not?—Yes, it is higher, but I do not exactly know how much; it would be upwards of 400 feet.

1401. What is the distance from the lake to Liverpool by the line you take?—I intended to take my supply at Llantysilio, which is 64 miles from Liverpool by a line of conduit.

1402. What fall did you give to your conduit?—I think 10 inches per mile.

1403. What would be the size of your conduit?—I do not remember now; I think it was about 10 feet wide; I intended to make it to take 60,000,000 gallons per day.

1404. You objected, did you not, to Mr. Bateman's conduit giving a fall of 12 inches per mile because it would tear up the whole thing?—It is no objection; I only say he could not work a conduit with that fall, he would have to put in arrangements to stop the velocity.

1405. Did you propose to put in those weirs?—I should have been obliged to do it, nature would have made me do it; I should very soon have found that out, but I was not as wise then as I am now.

1406. As far as you are able to judge, the capacity of this area of 289 square miles, and especially if the 38 square miles were added to it, would be equal to supply with water several large towns in Lancashire?—It would supply all the county.

1407. Do you think that the water of this district would be sufficient for the supply of the metropolis?—Yes; Mr. Bateman has thought all about it, but he has taken his other source because of the engineering difficulty about getting it there.

1408. Taking 4,000,000 as the mean population and allowing 30 or 40 gallons per head, what is your view as to the quantity of water per head, with regard to sanitary, manufacturing, and other objects?—You have about 100,000,000 or 108,000,000 gallons of water flowing into London per day now. My own impression is that more than a moiety of that water is wasted—is not used for any useful purpose.

1409. What do you consider to be a sufficient maximum quantity of water per head *per diem*?—There are 36 gallons per head now, and if the companies by bad arrangements of distribution waste half of it, that gives a volume that is used of about 16 or 17 gallons per head per day.

1410. I assume that if your plan were ultimately carried out for supplying the town of Liverpool with water, it would be a plan carefully considered and well calculated in all its details, and that there should be no waste in distribution?—That I would not undertake to guarantee. Waste must be checked by constant supervision after the works have been completed.

1411. Allowing a margin for waste, what quantity would you say was sufficient per head?—I should say 30 gallons per head.

1412. Taking the population at 4,000,000, is it your opinion, having regard to the area which you have coloured on this map dark and light blue, that that area would be equal to the supply of the metropolis with water?—That makes 120,000,000 gallons, and I say that you have with 48 inches of rain per annum flowing from the 289 square miles, about 550,000,000 gallons, passing under Llangollen bridge, so that you have nearly five times that.

1413. But of course you must leave a sufficient quantity of water to have some compensating powers so as not to destroy those rivers?—Yes; but you have a volume five times larger than the 120,000,000, and with a similar rainfall 48 in the 38 square miles will give about 72¼ millions of gallons per day additional.

1414. Then I understand generally there would be no doubt in your opinion that this area will yield a sufficient supply of water for the whole of the metropolis?—Yes, no doubt.

1415. (*Mr. Harrison.*) The level from which you would take the water being, as you say, 330 feet would not enable you to take it to London to give a high level supply?—No; besides there are intervening mountains between that district and London which would almost render it impracticable. There are the Berwyn mountains, that range right down between the Severn valley and the Dee valley.

1416. (*Sir J. Thwaites.*) Could you not take it to Stoke, as Mr. Hassard proposes, and there form a junction with his main culvert?—I have never thought that out, I have never paid attention to taking it to London.

1417. What is the level of Bala lake?—I do not remember, I know I put it down higher than it is.

1418. It is 530 feet?—Then you have 200 feet rise above Llangollen.

1419. If Mr. Hassard can bring it from Bala lake to London in connexion with his own tunnel, it is practicable for any one else to bring it and have an independent supply?—Yes, certainly. If it were a question of supplying London from this district, you can get it at the elevation which Mr. Hassard states it at, 450 feet, or whatever it may be.

1420. You mean taking the area which drains into the lake?—Yes, and a portion of the river a mile or two below it, and all its tributaries, and there are magnificient sites for reservoirs there, if reservoirs were required.

1421. (*Mr. Harrison.*) That would be an area in acreage of fully half what you put down there, but

yielding much more water per acre, a great deal of it being higher up the hills?—It does not follow as a matter of course, that you get more water because you rise.

1422. That I understand, but would not that particular district produce more water?—I think it would, because it has the first catch of the rain-clouds that come over from the Atlantic.

1423. (*Chairman.*) Are we to understand you that this scheme is now being taken up by the authorities of Liverpool?—No; it is simply that Mr. Duncan, the waterworks engineer, in consequence of the failure for the last two years of the works which they have carried out, at Rivington, the storage reservoirs falling much shorter than they had anticipated, and Liverpool and its suburbs having grown more rapidly than they anticipated, was called upon by the corporation to report as to the best district to supplement the supply, and in his conclusions he says that the advantages are in favour of Bala; beyond that they have not gone excepting by a resolution of the town council to request the engineer to see what additions can be made to their present means of supply, and to see if they cannot make them meet the wants of the time. They have not taken it upfurther than that, and Mr. Duncan simply gives an expression of opinion that it would be best to go to Bala if a change is made.

1424. (*Mr. Harrison.*) Supposing that water from either of the Cumberland lakes or from Bala lake, or from the Welsh mountains, of the softness of which it is stated to be, could be commercially brought to London, from your large sanitary experience do you consider that it would be a great object for the citizens of London to bring such pure and soft water to them?—I do; and I would go further than that and say that any person who has had the luxury of living and washing and using water in a soft water district, I think would willingly pay double his water rates if he was capable of paying them. I am speaking of persons who have the means of paying; I would willingly do so. Say that my water rates are now 6*l.* or 7*l.* a year, I would willingly pay 14*l.* a year if I could have the Manchester water to wash in for my ablutions, for its comfort and economy and pleasantness. I cannot describe the difference. Your skin feels more wholesome and comfortable, and you wash your hands with much more pleasure, and especially in the spring time of the year. You have not that wretched chapping which many persons suffer from. If you bring soft water for the first time into a place where people have been accustomed to use soap, ignorant people will complain about this water for a time that they cannot wash the soap off; instead of letting the soap alone they go and lather it on as they had been accustomed to before, and then they cannot get rid of it.

R. Rawlinson, Esq.
6 March 1867.

1425. (*Chairman.*) Have you any further information to give to the Commission which you think would assist them in their inquiry?—With regard to rainfall, I may say that I have examined the records of rainfall from all parts of the world where I could get access to them, and I have come to this general conclusion, although, of course, everything that is generalized must be taken with its grain of salt, that the seasons in any country will vary about as one to two. Take London, for instance, if your driest year is 16 inches your wettest year will run up to 32 inches, and then your medium will be 24. In Mr. Beardmore's book, where he gives the rainfalls of North America, India, Australia, the Austrian Empire, and many other places, I could point out dozens of instances where it is true. Ten or 15 years are not sufficient to test excesses of rainfall. Take it in round terms the seasons give about as one to two.

The witness withdrew.

Adjourned to to-morrow at 11 o'clock.

Thursday, 7th March 1867.

PRESENT:

HIS GRACE THE DUKE OF RICHMOND, K.G., IN THE CHAIR.

Sir JOHN THWAITES.	Colonel HARNESS.
Alderman Sir BENJAMIN PHILLIPS.	THOMAS ELLIOT HARRISON, Esq.

J. PRESTWICH, Esq.

ROBERT RAWLINSON, Esq., further examined.

R. Rawlinson, Esq.
7 March 1867.

1426. (*Chairman.*) Do you wish to offer any observations to the Commission in addition to your evidence of yesterday?—Yes; if the Commissioners will allow me, I will name a matter which has occurred to myself in reporting upon water supplies, namely, that in my opinion it would be advisable if engineers and others could come to some definite understanding with regard to a waterworks nomenclature. I see in the reports and documents words are used as synonyms which I think ought not to be so used. You will find that in these reports the word "quantity" is used with regard to water in volume, and the word "run" is used for water in motion. I cannot help thinking, though none of our dictionaries give us satisfactory definitions on this point, that it would lead to a clearness of conception if we used the word "volume" for water in bulk, and if we use the word "flow" for water in motion. I cannot conceive that it is proper to speak of water descending a conduit as running, because if we consider our language, we run with our legs, and running ought to imply a special kind of motion. I think the word "flowing" cannot be misunderstood. We say that water flows from a pipe, it flows down a conduit, and it flows down a river. But our language is rather loose in this respect. Every engineer and every literary man uses his own judgment, but in a report it would be well if words were used consistently. Occasionally the word "volume" is used, and then the word "quantity" for the same thing—water in *bulk* or *volume*. We say a quantity of potatoes, a quantity of coals, or a quantity of apples, but hardly with propriety, the quantity of water that is in the ocean. Perhaps the Commissioners will excuse my having mentioned this. In the report of the Commission of which I am a member, we adopted the rule to use "*volume*" and "*flow*" for water in *bulk* and in *motion*. I think the report reads more consistently.

1427. Have you any evidence to give the Commission upon the subject of the rainfall?—There are some general remarks that I was anxious to lay before the Commission. As the report of the Commission will be looked to with very great interest, and therefore a few broad general facts may be embodied in it which, although old news to adepts, may be of general interest, and the facts might not be noticed in the same way in which I shall put them. With regard to rainfall, I stated yesterday the broad general fact that rain varies, in seasons, about as one to two; and I said that after having examined the records of rainfalls from all parts of the world where they have been kept for any length of time, that I am borne out by the facts recorded. Engineers and others have got into the way of talking of averages, but averages of anything are liable to be very misleading, especially in meteorology. Liverpool,

R. Rawlinson, Esq.

7 March 1867.

for instance, was led to rely upon an average of rainfalls, but two or three consecutive dry years proved that it is the minimum which measures the capacity of the works, and not the average, because in such a case you are brought down to the minimum; the Liverpool people were told that they might rely upon 18,000,000 gallons per day after paying compensation. I think they were reduced for two years previous to this year, as low as from 6,000,000 to 8,000,000 gallons per day. Now that landed them in a very great scarcity; their reservoirs were nearly run empty, and if the drought had continued a very short time longer, they would have been under very heavy charges for compensation; they would not have been enabled to pay their compensations in water. If you take the fact that the years vary, as I state they do, from one to two, then if you have a minimum rainfall of 20, your maximum will be 40, and of course your average will be 30. If the average of years is given to you, and you want to know either the maximum or the minimum, by taking one-third and deducting it from the average that will give you the minimum, and adding it to the average will give you the maximum, as you will see very easily.

1428. (*Sir J. Thwaites.*) Is that borne out by Mr. Beardmore's tables?—I am giving you now what is not mathematically correct, and Mr. Beardmore says nothing about it; I am only telling how, if you have the average given, you may get approximately at the minimum or at the maximum.

1429. (*Mr. Prestwich.*) But you must know the maximum and the minimum before you get the average?—You may have the rainfall for 20 years; of course rainfall varies, it is 25 inches this year, 27 inches next year, 23 inches the year after, and then you strike an average; but you may have neither the maximum nor the minimum in any of those years.

1430. It is only from a known maximum and minimum that you can calculate the average?—Just so; but to get the maximum or the minimum the gaugings may perhaps range over a period of 50 years, but you do not always get it with a range of 10 years.

1431. (*Sir J. Thwaites.*) If you take your average for a period of 10 years, would you not consider that a fair average of rainfall?—No, certainly not.

1432. Is it your principle that in determining the quantity of water due to a given area you should fix upon the very smallest amount of rainfall in any part of the year or any part of a number of years?—You should fix upon the smallest annual volume of rainfall. Take for instance this great scheme; supposing you were going to tie London up to North Wales, and that you were going to rely upon storage, and that you were relying upon an average of any number of years. You have paid no attention to the minimum; you will find that you should have deducted one-third from that average.

1433. Pardon me, you have paid attention to the minimum, because that is an element in drawing your average?—Yes, but you have rejected that by taking and relying upon the average. I am supposing that you are relying upon the average.

1434. But all plus the average you know will bring up the minimum; what was the object of taking an average if it is not to produce that result?—But still do you not see that if you make works capable of storing and giving out the average rainfall, and if you proportion out your supply to the average rainfall as the Liverpool people did, when you come to have one, two, and three years of a minimum your average has simply been a delusion to you.

1435. Is not taking the average the first step to determine the quantity of water that you may reasonably expect from a given area?—No.

1436. Would not the next prudent step be to allow yourself a margin calculating the amount of water which you would probably require?—If you will do as I say, if you will deduct one-third from the average, whatever it may be, then you will make the margin which I say you ought to make, then you will have your minimum. If you take, for instance, the rainfall of a dry year at 30 inches, and if you take a wet year at 60 inches, that gives you 90, and half of it is 45. If you are relying upon 45 inches, because you have that average over a number of years, I say you must take 45 minus 15 which will give you 30, and then you must take your 45 if you want the maximum plus 15 which will give you 60.

1437. (*Chairman.*) You mean in taking those figures for example that the utmost outside quantity of water that you could calculate upon would be 60 inches, and that you could also make yourself quite certain that you would not be below 30?—The volume that you would have to fear for mischief would be 60, and the volume that you would have to fear for scarcity would be 30, or thereabouts; using these figures to indicate the probable, in special years there may be a few inches above or below the even numbers given.

1438. (*Sir J. Thwaites.*) Are we to understand that the object of the remarks which you have made with regard to the average of rainfall is to guard against the supposition that any scheme which professes to supply the inhabitants of any given town with water should not be calculated upon the average but that there must be a deduction, and of, in your judgment, one-third from that average as a proper deduction to make that quantity safe?—I think so, the same as I say is exemplified in Liverpool; they have been landed in a very grievous mistake because they relied upon the supposed average.

1439. (*Sir B. Phillips.*) What average did they rely upon?—I really forget; it is recorded in the papers, but their works were calculated upon an average and they have not realized it. They were told that they were to have 18,000,000 gallons a day, and that they were to do away with all their pumping stations, and to save about 25,000*l.* a year; they have never been enabled to do away with pumping, but have been obliged to increase it and to have a considerably larger amount of storage than was at first proposed.

1440. (*Col. Harness.*) Do you know how many days storage they have at Liverpool?—No, I do not remember; I think it is about 120. There is another fact with regard to meteorology which is not always attended to, which is sometimes forgotten, namely, the fact of excessive rainfalls, and the danger of excessive rainfalls. Great destruction occurs in this country at intervals by excesses of rainfalls. There is a prevailing notion all over the country that something or other has occurred to alter the seasons in this climate. It was quite curious that when the Rivers Pollution Commissioners were holding their inquiry in Yorkshire, during our first sittings we had evidence from all sorts of people to that effect, that land drainage, making storage reservoirs, and general cultivation had so altered the character of the country and the climate, that there had been no floods anything like the floods which occurred formerly, and the witnesses did not expect that there would ever be such floods again. Before we concluded our course of inquiries in Yorkshire, while we were sitting at Halifax that great storm occurred which is said to have done damage to the extent of from half a million to a million sterling in the valley of the Aire and Calder alo ne,showing how falsely the reasoning had been that nature had changed its character in consequence of the little puny efforts which men have made upon the surface, and I think that fact should be strongly impressed upon engineers and others who have to contend with the elements. We may rely upon it there is nothing that we can do upon the surface of this globe which will have anything but an infinitesimal effect in altering meteorology; it is independent altogether of our efforts. We may alter it in its small falls, but certainly we do not touch it in its excesses. That flood which occurred in Yorkshire last autumn was as destructive (in fact more destructive, because there was more property to destroy) as any we have any record of; it did incalculable damage, and it has done damage which might have been prevented if a proper and wise forethought had been taken

and proper arrangements had been made to guard against such excesses. If people had not blindly brought their property into danger, and gone on as they were going on, a good deal of the damage might have been prevented. Leeds, in some low parts, was six feet under water, and they were carrying provisions, lights, and fire about in boats to the poor wretched inhabitants who were confined in their houses. We had evidence from manufacturers, that in some of the valleys within the last 20 years they had lost more by floods than the whole worth of their property. In Todmorden, right up in the hills, we went through some large weaving sheds and workshops where looms, carding machines, and other engines, worth hundreds of pounds, had been destroyed; the water had been four feet high in the workshops. All that could have been guarded against by proper works and proper regulations. Bridges are washed down, culverts are blown up, and all this mischief is done because people choose to forget that nature now and then runs into those excesses, that she has done so before, and that she will inevitably do so again.

1441. (*Chairman.*) Does that apply as an objection to any particular mode of storing the water?—I should say that where you contemplate making such lakes as Mr. Bateman speaks of upon the upper Severn, if they are not made with a full knowledge of what nature will do in her wildest excesses, it is quite possible that those banks will be swept away like leathers. In North Wales during the time I was making an examination for my Bala lake scheme a storm occurred one night upon the Berwyn mountains in 1846, and the effects are seen at this moment. The rain began in the evening, it continued all through the night, and it brought down thousands of tons of stones and gravel; it left the old watercourses and it broke out new ones; it swept the débris down from those Berwyn mountains; and it levelled the village of Corwen up to the eaves of the houses, the church and all, and so they remain to this day; they were obliged to be cleared out and they are like cellar dwellings. The flood brought down thousands of tons of solid matter in that single night, and it carried bridges away which had stood beyond the memory of the oldest man.

1442. (*Sir B. Phillips.*) I thought I understood you to say that these reservoirs might be built imperishably, so that they may stand for all time?—Then they must be built very differently from anything that I have seen in modern times.

1443. I am speaking of the fact as to whether they can or cannot be so constructed as to defy the destructive element of which you speak?—I believe that they can.

1444. Then your observation is merely directed to this fact, that if they are not built of sufficient strength to resist what you call the volume of water at certain seasons they may be very dangerous, in other words that they would give way altogether?—Just so. For instance, those rains last autumn swept a large stone viaduct down in Yorkshire, which I say is a disgrace to the engineering science that put it up. There is a wide valley there, and a magnificent looking stone reservoir was swept helplessly down in one night.

1445. (*Sir J. Thwaites.*) Supposing that the dams are made with proper care and proper material, of sufficient strength, and with all the proper sluice arrangements and storm outflows so that the pressure would not be increased upon such dams; is there much fear that those dams will be carried down by such storms?—Not if those wild excesses of nature are contemplated beforehand and provided against.

1446. You would not have more hydraulic pressure if your reservoir is filled and if you have sufficient means of escape to meet those wild excesses to which you refer, then the dam would not be injured?—No, it might not; but as I say the dam must be built upon very different principles from those which I have seen.

1447. But you would always assume that any engineer of intelligence having regard to the experience of the part would build his dam with care and with proper materials?—I do not assume anything of the kind; I am afraid I must assume the contrary. I feel bound to speak to you as strongly as I can use language. I do not assume anything of the kind, I wish I could.

1448. (*Chairman.*) You have given the Commissioners, have you not, the period during which you would be satisfied with gaugings being taken to give an average of the rainfall in any particular district?—You cannot get the excesses, the maximum, and minimum that a country will give; if you do it is quite accidental, under 40 or 50 years, you certainly cannot rely upon any gaugings for 10 years.

1449. You would not be prepared to say that no scheme should be sanctioned till the rainfall has been taken for 20 or 30 years?—No, unless an engineer was determined to push a scheme forward on which he was taking the margin given him by four or five years rainfall; I should recommend him certainly to make a very considerable deduction and to take off at least one-third of his average for that period.

1450. Are we to understand you to say that one-third taken off and one-third added would be equivalent in your estimation to the experience of 20 or 25 years?—No; there must be a liberal deduction to make any engineer safe.

1451. (*Sir J. Thwaites.*) In the case of your scheme conceived 20 years ago with reference to the supply of Liverpool from Bala lake, was that subject to a deduction of one-third, or was the margin so great that your attention was not directed to that point?—The margin was so great and the area was so much in excess of what was required, that it was not necessary for me to do so.

1452. (*Chairman.*) Have you any other point which you wish to put before the Commission?—With regard to maximums and minimums of flow, Mr. Bateman's evidence agrees with my experience and evidence. In this country and in this climate (surfaces of chalk, oolite, and some others excepted) the dry weather flow is to the wet weather flow as 1 to 300 in ordinary periods, and as 1 to 500 and 600 in excesses. Mr. Bateman names 1 in 1,000, and I have no doubt that he is correct for limited areas. If you have an ordinary stream in dry weather, giving you any volume of water, the flood in that stream will be 300 or 400 times that volume, and it may rise for a short time up to 600 or 700, and even to 1,000. I do not mean for 24 hours, because the mischief is done in seconds. Then, although in this climate you have nothing like the tropical monsoon rainfalls for continuance, and the rainfall in this climate varies from the wettest part in Cumberland of 150 inches to the dryest on the eastern coast of about 17 inches, yet you may have as violent an excess on the east coast of England, with its 17 inches of rainfall, and as much mischief, if sufficient precautions have not been taken, as you will have in the wettest district with its 150 inches, or amidst monsoon rains, because thunderstorms, which are common, and occur all over the country, are as capable of pouring down as violent an outpour of water in this climate as a thunderstorm can pour out in the tropics. We have had instances in London in which two inches of rain have fallen in about half an hour, four inches in the hour—there you have the element of destruction in its concentrated form. I very much question whether, taking time into account, you could get a heavier rainfall in any part of the world.

The witness withdrew.

Professor J. T. Way.

7 March 1867.

Professor JOHN THOMAS WAY examined.

1453. (*Chairman.*) You are a professor of chemistry I believe?—Yes. I am not attached to any college at present. I am an analytical chemist, and I am a member of the Rivers Commission.

1454. Have you made any analysis of any of the waters in the lake district or in the Welsh district?—I examined some waters for Mr. Hemans' and Mr. Hassard's plan, which analysis I have given in this pamphlet of Mr. Hemans, at page 13, and I think the Commission have had it in evidence. There are four samples of the water; from the river Lowther, from Haweswater lake, from Ullswater lake, and from Thirlmere.

1455. What is the character of the water taken from those places?—The waters of the three lakes have a character very much alike; they are soft, bright, good waters. The river Lowther differs a little, but still it is a fairly good water; not so good as the others, but a very fair water.

1456. What is the number of degrees at which you would fix water as being soft or hard?—The water which we use in London from the companies is 13 or 14 degrees of hardness on the average; that, in Yorkshire, would be called very hard water, for in the districts of the west riding of Yorkshire the water is usually from 2 degrees of hardness up to 7 or 8 degrees, but 13 degrees of hardness is not a hard water as compared with many waters which are in use for domestic purposes in the country whose hardness would be from 30 to 40 degrees perhaps.

1457. I think we have it in evidence that what is commonly called hard water is anything in which there is 6 degrees of hardness, and that anything under 6 degrees would be soft?—That is a purely empirical standard, of course. I think the question of hardness would have a reference more to habit than anything else, at least what anybody would call hardness. Water with 2 degrees is certainly soft, and water with 18 or 19 degrees is certainly hard; but whether water should be called hard when it is 10 degrees, or when it is 13 or 14 degrees one could hardly say. There is a great advantage in the water which is 2 or 3 degrees over the water that is 12 or 13 degrees, like the water of London at this moment.

1458. Do you consider that water, which is, as you say, 2 or 3 degrees, much more healthy or more economical?—It is more economical. It is exceedingly doubtful whether it is more healthy, because people are in the habit of drinking waters of 17 or 18 degrees of hardness without any apparent injury to health; indeed, they are the most beautiful waters as drinking waters. The waters that are the brightest and the most liked are the hard waters, the chalk waters.

1459. Have you analysed any of the waters in the northern part of Scotland?—No, not to my knowledge; not of late years at all events. I think that the question of the effect of hard waters upon health is quite an open one. There is no reason to believe that chalk water is injurious except, I believe, in some instances, such as in the introduction of goitre. There are cases I believe in the valley of the Thames in which hard water is said to produce that effect; but the advantage of soft water for domestic use is very obvious, both in comfort, and also in economy, and for cooking purposes. So again for all purposes where steam boilers are in use soft water is much more economical, inasmuch as the boilers do not get foul.

1460. If you had your choice to provide a large community with water, and you were able to get with equal ease hard water or soft, you would prefer the soft water?—Undoubtedly. I should go further than that, and say that water that is hard ought to be softened if it is possible to soften it.

1461. (*Mr. Prestwich.*) Do you mean for genera purposes, excepting the question of health?—No, I do not attach anything one way or the other to the question of health, that is to say, where the hardness is in moderation, where carbonate of lime is the hardening ingredient. But where you have water with 80 or 90 grains of sulphate of lime in a gallon, as you sometimes have, that is another question entirely.

1462. You would consider, would you not, the presence or the absence of organic matter to be the essential point?—Yes, as far as health is concerned, I should.

1463. According to your analysis the Cumberland waters show a very small quantity of organic matter?—Yes, that is so.

1464. (*Chairman.*) What portion of organic matters is there in the waters which are supplied to London?—They differ at different times, but they are very much more considerable than those in the lake district. We have the records of Dr. Frankland's analysis as published by the Registrar-General, from which it appears that they are generally rather above one grain in the gallon, and sometimes considerably above one grain. The waters of the lakes are a little below half a grain—one of them is above half a grain.

1465. (*Sir B. Phillips.*) How many degrees of hardness are the lake waters?—Haweswater is 2 degrees of hardness, Ullswater 2·1 degrees, and Thirlmere 1·5; those are as soft as any natural waters are.

1466. (*Mr. Prestwich.*) Do you find those waters well aërated?—Yes.

1467. You have not given the quantity of oxygen, have you?—No, the quantity of oxygen has not been determined.

1468. (*Chairman.*) How much water, in an analysis such as you have made, is necessary to enable you to come to a satisfactory conclusion?—From two to four gallons, or you can do with less even.

1469. Are you able to say whether those waters were taken at any one particular time or at different times?—They were taken at one time. I know nothing of the collection of them; they were forwarded to me.

1470. You only know that a certain quantity of water was given to you?—Just so; they reached me at one time.

1471. They were stated to come from those places, and you analysed them?—Yes.

1472. And this is the result of your analysis, which may be found in the 13th page of Mr. Hemans' and Mr. Hassard's pamphlet?—Yes.

1473. And your opinion is expressed in a letter which accompanied them, dated March the 21st, 1866, addressed to G. W. Hemans, Esq., at page 14 of the pamphlet?—Yes.

1473*a*. Will you have the goodness to hand in your analysis and the accompanying letter?—(*The witness delivered in the following tables*):—

GRAINS PER IMPERIAL GALLON.

	River Lowther.	Haweswater Lake.	Ullswater Lake.	Thirlmere Lake.
Lime	1·54	0·50	0·81	0·42
Magnesia	0·50	0·18	0·20	0·14
Soda	0·80	0·71	0·51	0·46
Chlorides of Sodium and Potassium	0·48	0·40	0·69	0·77
Oxide of Iron, Silica, &c.	0·50	0·25	0·20	0·05
Sulphuric Acid	0·51	0·51	0·37	0·44
Carbonic Acid	2·05	0·82	1·03	0·56
Organic Matter	0·62	0·62	0·35	0·77
Total Impurity	7·00	3·99	4·16	3·61
Hardness before boiling	5·2°	2·0°	2·1°	1·5°
Hardness after boiling	4·4°	1·8°	2·1°	1·5°

These substances are probably combined as follows:—

GRAINS PER IMPERIAL GALLON.

	River Lowther.	Haweswater Lake.	Ullswater Lake.	Thirlmere Lake.
Carbonate of Lime	2·75	0·90	1·45	0·75
Carbonate of Magnesia	1·05	0·36	0·42	0·29
Carbonate of Soda	0·70	0·56	0·40	0·20
Sulphate of Soda	0·90	0·90	0·65	0·78
Chlorides of Sodium and Potassium	0·48	0·40	0·69	0·77
Oxide of Iron, Silica, &c.	0·50	0·25	0·20	0·05
Organic Matter	0·62	0·62	0·35	0·77
Total Solid Matter	7·00	3·99	4·16	3·61

106, Leadenhall Street, E.C.,
March 21st, 1866.

DEAR SIR,

I ENCLOSE the analyses of the waters of the river Lowther and of the three lakes, Haweswater, Ullswater, and Thirlmere.

As might have been expected, none of them show more than a small proportion of solid matter per gallon; the river Lowther is the least praiseworthy on this account, though even that sample contains only seven grains of total impurity per gallon.

The proportion of organic matter in all the samples is small; the water of the river Lowther is, however, slightly coloured, no doubt from peat.

The waters of the three lakes are as soft as any natural waters can be; the water of the river Lowther does not equal the others in this respect, but as compared to the usual towns' supplies, would be considered a soft water.

On the whole, I have no hesitation in saying, that any one of these waters, or a mixture of them, would be admirably suited for the domestic supply of town populations, whether large or small.

I am, &c.

G. W. Hemans, Esq., C.E. J. THOMAS WAY.

Professor J. T. Way.

7 March 1867.

1474. Have you seen any reason to alter the opinion expressed in the tables?—None at all. I might add that upon the river Lowther there are some lead mines in the immediate neighbourhood of Ullswater, and those samples were tested for lead, and that should have been so stated in the letter sent to Mr. Hemans; they were tested for lead with a view to ascertaining any injury that might arise from that cause, but lead did not exist in those samples.

1475. (*Sir J. Thwaites.*) But the washing from the lead mines passed through the lake, did it not, before it arrived at the point where those samples were taken from?—I do not know how that was. The lead mines are not on the river Lowther, and it seems that the river Lowther is not subject to the action of the lead at all.

1476. The water from the washing of the lead is discharged into the upper part of the lake, and traverses the whole lake, does it not, before it arrives at the river Lowther?—Yes; however, I can speak to this, that it does not exist in any of the four waters. The sample in question, I am informed, was taken in the middle of the lake.

1477. (*Chairman.*) In fact, in the four samples which were sent to you, you did not find lead to exist?—No.

1478. (*Mr. Prestwich.*) That water was collected in January; have you any reason to suppose that the quality of the water would differ according to the seasons of the year?—No, I fancy not; probably it might be a little more discoloured with peat at some times of the year than at others, for instance, in the late autumn or the winter.

1479. (*Col. Harness.*) How small a quantity of lead would your process have detected?—I cannot tell you, but it would be extremely small; anything that would be likely to be prejudicial to health would be readily detected.

1480. (*Sir J. Thwaites.*) Do you anticipate any improvement or deterioration in the value of the water in consequence of the mode of conveying it to London through tunnels, aqueducts, and so on?—I have not inquired into that question, but I should think not. I cannot see why the water should suffer from that cause.

1481. (*Chairman.*) Have you ever analysed any of the waters which are found in the district of North Wales, which Mr. Bateman's scheme proposes to take?—I have not analysed those which are spoken to in Mr. Bateman's pamphlet.

1482. Have you ever analysed the waters in that district?—I examined the water in Bala lake some years ago, but I could not speak authoritatively of any of those waters. I have had a large experience in the analysis of waters throughout the country.

1483. Should you say, speaking generally, that the waters in Wales would resemble very much the waters in the lake district?—I should think they would. The analysis would speak for itself, but waters flowing from different geological strata, of course, would differ in composition.

1484. Have you formed any opinion as to what would be the best geological strata from which to obtain water?—That depends upon whether you have reference to any particular town or are merely speaking in the abstract.

1485. Taking it in the abstract, what should you say?—I know of none like the millstone grit.

1486. When you say "any particular town," what do you mean?—Not having reference to this particular inquiry, I should say that the best geological district which I know for water supply is millstone grit, but that answer would not apply if you wanted to bring water from millstone grit to London.

1487. Taking it in the abstract, if you wanted to find out the best water, where would you go?—The waters in the district which we have been examining on the Rivers Commission, viz., those of the West Riding, are the best waters naturally. They are the foulest waters in the kingdom as they stand at this moment, but naturally they are the most beautiful waters I have ever met with.

1488. (*Mr. Prestwich.*) Of what degree of hardness are they?—The springs in the hills are under two degrees of hardness.

1489. Have you any reason to suppose that waters so soft as those would act upon the pipes?—That is a very doubtful question. I do not think that these waters would, but my answer would be that there should not be any leaden pipes to be acted upon.

1490. But how would it be with regard to their action upon iron pipes?—All water, whether hard or soft, will act upon the pipes if they are alternately full and empty, and soft water will act very rapidly upon iron pipes under such circumstances.

1491. (*Sir J. Thwaites.*) Take leaden piping, for example, which is constantly charged; would not it become coated very soon, and the lead be protected by the oxide?—Yes, that is so; but in the case of leaden cisterns you have the action, of course, at the surface of the water, where the air has access to the lead at the same time.

1492. (*Col. Harness.*) Is water which is kept in an open iron cistern injuriously affected by the iron?—I think that iron cisterns are apt to rust if they are not covered with asphalt. I have known cases where iron pipes with soft water have been entirely destroyed in a year or two from lying on the side of a hill where they were alternately empty and full, in fact, half full and half empty.

1493. (*Sir J. Thwaites.*) You would not think that a little iron was objectionable to the human frame, would you?—Not for drinking purposes; the pipes are injured, but the iron does not get into the water; it rusts into oxide of iron, which makes the water turbid, but it is not dissolved.

1494. (*Mr. Prestwich.*) Has it not been found that in some towns the iron pipes have had to be renewed in the course of a few years from the action of water upon them, as, for instance, in the case of Grenoble, where I believe that occurred?—I believe that it is quite likely, but in those cases, I think, it would be found that the water is not supplied upon the constant system, and that the pipes are not always full of water. I can mention a case which actually occurred with the water of the Surrey sands, the Bagshot sand at Farnham. A friend of mine, Mr. Paine, laid down water from some moor or common land above Farnham, to supply the town, and iron pipes were used. The water came down very freely, but the pipes, which were three or four inch pipes, were only partially filled, and in two years they were entirely destroyed by the soft water. You might consider that there was a current of air passing up the pipes at the same time that the water was coming down and the action of the air and the water together destroyed the iron. It is a well-known fact that iron in an unprotected ship is destroyed much more at the water line than it is either above or below.

1495. (*Sir J. Thwaites.*) I presume that the oxidation would not go on if the air were excluded?—If you

Professor J. T. Way.

7 March 1867.

put a piece of iron into aerated water, and seal it up so that no fresh air can get in, the oxidation goes on to a certain extent and then ceases altogether. The iron has no power of acting upon the water to get oxygen, but only on the air dissolved in the water. I believe that the constant supply system would be the corollary of the soft water and iron pipes.

1496. (*Mr. Prestwich.*) If it removed the oxygen from the dissolved air would it not render the water less suitable for drinking?—Yes, but it takes from and it does not add. Iron pipes are becoming now very constantly adopted in water supply. In this last week I have bought a house at Kensington in which every pipe in the house is iron; there is not a leaden pipe in the house at all.

1497. But in your case is the water comparatively hard?—Yes, but I should not fear any injury if soft water were substituted, providing that the air is kept out of the pipes. The air that is in the water would not do any substantial injury to the pipes.

1498. Though it may not injure the pipes would it not be likely to injure the water by the removal of that which constitutes an essential element in good drinking water?—You could not have the one without the other. If you remove the oxygen it would be by oxydation of course, and therefore the pipes would *pro tanto* be injured, but I should not fear that. One advantage of soft water would be the necessity for caution against lead; that is to say, we should get rid of lead as a means of supplying water which I think would be very beneficial indeed.

1499. Have you had much experience with regard to the desirability of using soft water for manufacturing purposes in preference to hard water?—There is no doubt great advantage in soft water for most manufacturing purposes.

1499*a*. Could you name the trades in which you would consider soft water preferable?—In trades of which I have seen a great many examples lately, in Yorkshire, for instance in dyeing, they prefer soft water to hard water, in fact, I presume, they went there for the soft water, and for washing the goods after dyeing; the quantity of soap consumed is immensely large even now in Yorkshire. A manufacturer will use as much as 1,000*l.* worth of soap in one mill in a year, and if he had hard water he would use perhaps 2,000*l.* or 3,000*l.* worth, and that has a very serious effect upon the price of goods. Soft water is not good for brewing; it is good for the darker kind of beers because a larger extract is obtained by it, but it will not brew bitter ale or light coloured beers, in fact, all the Burton beers are brewed with hard water.

1500. (*Sir B. Phillips.*) Is soft water desirable in London for the porter brewers?—I should think it was. It is only undesirable so far as colour is concerned; there are some waters which produce beer of a dark colour. I remember the case of a brewer who had been making beer of a moderately light colour, but having a necessity for more water, sunk an artesian well. Artesian wells coming from the chalk generally have some soda in them, and when he began to brew with the water from this artesian well he got a very large extract as it is called, that is to say, he got a great quantity of material from the malt, but the beer was so dark that it was unsaleable. In the case of porter brewing the quantity of extract is the real thing which is desired, but in the case of pale ale brewing the colour is the essential point.

1501. Have not the London brewers some material with which they colour their beer; it is not naturally of the dark colour that we see it, is it?—It is the colour of the very highly dried malt which gives it the black colour; it should be so, and I suppose it is so. The organic matter in the malt is half way between its ordinary state and that of real charcoal. It is not charcoal or it would only give an insoluble colour, whereas porter if filtered still remains dark coloured.

1502. But the malt is charred is it not in order to produce that colour?—It is heated strongly; in fact it is like burnt sugar.

1503. (*Chairman.*) Do you think that soft water would save the brewers the trouble of that charring operation?—No, it would give them a greater strength of beer extract, so to speak, from a given quantity of malt and the colour would not be objectionable, but it would not make the dark colour of porter.

1504. (*Mr. Prestwich.*) With regard to dyeing, is it not also very much a question of economy in the saving of soap rather than in the colouring of the dyes, as would appear to be the case at Lyons, for example, where the dyers use water of a considerable degree of hardness, and when it was proposed to give them softer water they preferred to use the harder springs which contained a larger proportion of carbonate of lime?—I believe that in the case of some of the bright colours a harder water is preferable, and for the very same reason that it is for beer, namely, that the lime precipitates some of the darker colours. Hard water makes considerably better tea than soft water. That is not the general impression; the impression is that soft water makes a stronger tea. It certainly makes a darker coloured tea, but you get a much better flavour from tea made with hard water. I should, perhaps, have qualified what I have said about dyeing, by saying that for the dyeing proper, especially in light colours, hard water is not objectionable, but I refer to the process taken as a whole. The washing requires so much water that should be soft that on the whole soft water is infinitely preferable.

1505. With regard to tea, we have been told that there is great economy in the use of soft water for tea; do you agree with that?—In saying that that is not so, I should, of course, contradict every practical person; most women would tell you that soft water makes the best tea. It does not make the best flavoured tea by any means, because soft water dissolves a quantity of bitter extract which makes the tea strong—but to a refined taste hard water makes the best flavoured tea.

1506. You think the tea would go further, but would not make so pleasant a beverage?—Not so refined a beverage; it makes a darker coloured tea and satisfies the wants of persons who can only afford a certain quantity of tea.

1507. (*Col. Harness.*) Is there some particular quality in tea which is drawn out by one water and left by the other?—Yes, it is a peculiarity of lime salts, aluminous salts, and some others to combine with the tanin, and the bitter principle of tea, and other matters of that kind, and to separate them from the solution.

1508. (*Chairman.*) You think that hard water brings out a better flavour and that the colour is merely a matter of fancy?—It is the flavour that the hard water leaves behind undeveloped that is really the difference between the two; the soft water dissolves a great deal more of the tea. It dissolves the same bitter matter in the first instance which you get in all cases when the tea has stood very long. Everybody knows that to taste tea in perfection you should taste it as the tea tasters do, that is, by pouring boiling water on a good deal of tea and pouring it off immediately. If you leave the water long on the tea it dissolves the bitter matter, and soft water dissolves the bitter matter more rapidly than hard water. It is not in the flavour that it gives, but in the objectionable flavour which the hard water leaves behind and does not give that the advantage consists; soft water dissolves the objectionable matter, whereas hard water does not.

1509. (*Sir B. Phillips.*) It is what is commonly known as the rough flavour which soft water extracts from the tea, is it not?—Yes, the active principle of tea is dissolved by soft water or hard water equally; that is to say, the principle which has the exhilirating effect.

1510. If people were to take tea in the same way that tea tasters do, you think that it would be necessary that it should be made with hard water?—Yes.

1511. Soft water would not have the same effect?—No. Soft water would give the true aroma of the tea, but it would be mixed with the bitter principle.

1512. (*Sir J. Thwaites.*) If your principle were to prevail our grocers bills would increase very rapidly I presume?—Yes; I know perfectly well that soft water is considered to be a great advantage for making tea, but it is not so for those who can afford to make tea good.

1513. (*Sir B. Phillips.*) That is to say, when you use hard water you want a large quantity of tea to give the same strength?—The drinking of tea is a conventionality like many other things, and people are accustomed to taste the bitter taste of tea and are satisfied with it.

1514. And that is extracted by soft water more readily than by hard water?—Yes, but if you wished to enjoy the flavour of tea you would make it with hard water.

1515. (*Sir J. Thwaites.*) If you want to catch the fine flavour of tea you would make tea with hard water, but if you consider economy you would use soft?—Yes, because the tea looks stronger and tastes stronger; it is not stronger for the object for which you really take tea. Tea and coffee have both an active principle, which in tea is called théine. It is a crystalline substance, like quinine, and whether it be hard water or soft water you dissolve that principle, but along with that principle, which is the really effective agent in tea on the animal economy, you dissolve other things which you might just as well leave behind, so far as the effect on the digestive organs is concerned.

1516. (*Chairman.*) Good tea, plenty of it, and hard water is your principle?—Yes; the saving of soap from using soft water cannot be denied for a moment, and also the saving of linen. The clot produced by lime attaches itself to calico and linen and to ordinary things which are washed, and tends to injure the fabric very much.

1517. (*Sir J. Thwaites.*) Was your attention turned to the process of scouring cloth when you were in Yorkshire?—Yes, a good deal.

1518. Are they not obliged to use a large amount of soap for the purpose of getting rid of the greasy matter?—Yes, and a great deal of that they recover now, but not so much as they should. In many mills in Yorkshire there are contractors, who take the soapsuds and add acid to it and get the grease back, and we were informed that upwards of 100,000*l.* worth of material a year is so saved in the West Riding.

1519. Soft water in that case would therefore be a matter of the first importance?—Yes. I believe the manufacturers of Yorkshire went to the different streams in the valley of the Aire and the Calder solely for the soft water. No doubt the supply of coal had some influence with them, but the trade settled itself down there principally on account of the bright, clear, and soft water. If it had been a question of coal only they would have gone into Staffordshire, but it is water that they want more than coal, and they have actually killed the goose that laid their golden eggs, because the water of many of their streams has been rendered so foul by these processes that they cannot use it for washing purposes. They do in some cases, but they get as much water as they can from wells and town supplies, which are derived from other sources than those streams upon which the mills are situated.

1520. Is there a general desire on the part of the manufacturers of that district for an independent supply of soft water?—I think they would like an independent supply, for they get it at great expense, and they must always have it. The tendency of the manufacturers is to go over each others heads up the streams; that is to say, if there be a portion of a stream with pure water (not for water power but for use in the manufacture) a man goes past his neighbour and locates himself, if he can, higher up; but that has almost come to an end. They have their mills along the little rivulets and streams up to the very tops of the hills, and it is difficult to say where they are to go for larger supplies of water for manufacturing purposes whilst they are so thickly populated on their own streams.

1521. Supposing a supply could be obtained from the lake district, would it not be desirable for manufacturing purposes and the health of the inhabitants?—I think that the remedial measures should rather begin at the other end; that is to say, to prevent the fouling of rivers by their processes, and it is upon that that our hope of doing any good in Yorkshire is founded. For the purposes of the manufacturer the streams would be sufficiently good if attention were paid to preventing the pollution by each manufacturer.

1522. How are they to get rid of their washings?—That is a problem which is under our attention at this moment. I have under my control, as one of the Commissioners, some experiments at Huddersfield, in which we are taking the black dye liquid, which is as black as ink, and endeavourirg to get rid of the discolouration.

1523. Have you tried the sump system of subsidence?—It has been tried in one or two cases, but very unsuccessfully. The black dye water is discharged in many hundred thousand gallons from mills; in fact, a little mill will discharge more than 3,000 gallons a day quite as black as ink into the river. Some attempts have been made to let it subside, and to run off the clear liquid. Mr. Ripley, who is a very large manufacturer at Bradford, gave us evidence on that subject He has large tanks, in which he allows a certain amount of this material to subside, and the water flowing over goes to other mills for other general use. But that is not successfully done in any case; the difficulty is to know what to do with the sludge when it has subsided. Mr. Ripley, after collecting it for a fortnight, sends it all out on Saturday afternoon into the river, so that it is merely concentrating it for the sake of getting clearer water during the interval.

1524. So that all the local streams are polluted?—Yes; there are very few streams that are not seriously polluted.

1525. Does not that condition of things render it necessary that they should have an independent supply?—If it is not wandering from the subject, I may say that we have the fullest hope that we shall enable each manufacturer so to deal with the water which he takes in, and which he fouls in his operations, that the rivers shall be fit for their use.

1526. Do you mean for domestic purposes or for manufacturing purposes?—For manufacturing purposes; hardly, perhaps, for domestic purposes. But it is a remarkable fact that the water in the rivers of the rivers of the West Riding of Yorkshire, when filtered, is exceedingly good water, in spite of all the contaminations that are thrown into them. I am engaged at this moment in making practical experiments to separate the solid matter of the black dye water; a little lime is added, a couple of hours subsidence takes place, and the water is as clear as water. There is a slight tinge of yellow in it, but it is perfectly fit to be thrown into the river.

1527. You precipitate, do you, all the matters in suspension?—Yes.

1528. How do you deal with that which is in solution?—The matter in solution is really unobjectionable, as far as the rivers are concerned; I do not mean for domestic purposes; but manufacturers say that if that water is thrown into the river, the black stuff being kept out, they will be able to use the river water, and that of course will liberate a great quantity of water for domestic purposes. The competition between the manufacturers and domestic necessities at this moment leads to a high price for both waters.

The witness withdrew.

B. Denton, Esq.

7 March 1867.

BAILEY DENTON, Esq., examined.

1529. (*Chairman.*) You are a member of the Institute of Civil Engineers and have had extensive experience, have you not, for upwards of 25 years in drainage, &c., in various parts of England and Wales?—I have, and it is in consequence of that experience, which has made me acquainted with nearly every river basin in England and Wales, that I venture to present myself to this Commission as a witness with regard to the subject now before it. The effect of drainage, as developed in my own proceedings, bears very largely, as everyone must admit, upon the question of water supply; and as there is a great change taking place in the country by the drainage of lands and the drainage of towns, the one in affecting the quantity of water and the mode in which it is discharged into the valleys and into the rivers, and the other in polluting the waters of rivers, it must be obvious to everyone that the effect on the water supply from both causes must be equally great. In the course of my proceedings in connexion with drainage I have become much impressed with the great importance of water supply (I call it water economy) to the country generally. I am led to infer from the attention which is now being expressly called to the supply of large towns that a very disadvantageous influence will be experienced upon the supply to small ones, and it was in order to lead the authorities of this country into the consideration of the whole subject that I have been induced on more occasions than one to speak of the change taking place.

1530. Before you go into that allow me to refer you to the paragraph in our Commission which directs us what our inquiry is to be and which excludes from it everything but the metropolis and the larger towns?—I do not propose to dwell upon the supply to any of the smaller towns, though I do wish to show that even with respect to the supply to the metropolis and the supply to all towns, large as well as small, drainage in its various phases is having its effect, and as you are dealing with the metropolis which is now supplied with water from the Thames and its tributaries which are and will be more largely affected by drainage, I should hardly think that you could exclude that subject from your inquiry, but if you think otherwise I have no desire to intrude my opinion upon the Commission.

1531. At present our duty is to ascertain what supply of unpolluted and wholesome water can be obtained by collecting and storing water in the high grounds of England and Wales by the aid either of natural lakes or reservoirs at a sufficient elevation for the supply of the large towns?—I observed that, and in my addressing your grace upon the subject, I felt some doubt whether the views that I entertained would be acceptable to this Commission.

1532. It is not a question of what is acceptable to us, but we are appointed to perform certain duties which are laid down by the terms of the Commission and we are bound to inquire only into the matter which is referred to us?—Would the Commissioners permit me to explain how far I think that the question submitted to you has reference to the points that I would touch upon. I am prepared to show that the upper streams of the Thames basin, the tributaries of the Thames, are capable of supplying the metropolis if supplemented by storage, and that that storage would partly consist of the water of under-drainage and the water of drainage by arterial improvements from the upper lands which form the margin of the Thames basin. I should state, however, that my proposal is to take from the Thames and its tributaries, at points above which water may be obtained in positive purity by the proper exercise of conservancy, all that may be required for the supply of London, having stored in winter the surplus waters of that period of the year in order to repay the river system in summer what may be required to maintain it at a fixed standard height.

1533. What is the height of the ground above Ordnance datum from whence you would get this water?—The height of Lechlade, which would be the highest point from whence the collecting conduit would start to bring the water from the high grounds to London, is about 210 feet 6 inches above Trinity datum.

1534. Could you give us the Ordnance datum?—It would be 12 feet 6 inches below that. If you consider that 222 feet 6 inches, being the highest point from whence the collected waters would start, is not the high ground referred to in the terms of the Commission, any information that I may convey or any opinions that I may express are of course beyond the inquiry.

1535. The Commission have been proceeding throughout the inquiry on the supposition that the water when it reaches London must be at a height of 200 feet?—As the point from whence my collecting conduit starts is only just about that height that condition cannot be fulfilled within the Thames basin, but if I can show you, as I hope to show you, that there is an ample supply within the Thames basin, then the question of quantity will be satisfied. The quality, with regard to hardness, is a point to which I might speak, but it is not the point upon which I wish to lay the greatest stress, because there are chemical means of overcoming hardness if it be considered a *sine quâ non* that the hardness of the Thames water should be overcome.

1536. You start by your highest point being 210 or 212 feet above Trinity datum; what is the distance from London?—The distance is 127 miles, the fall being something like 20 inches per mile.

1537. And is the height when you get to London to be 200 feet?—No; I look upon the question of high service to be one quite apart from the question of the source of supply, and one upon which the water companies must satisfy the just demands of the public.

1538. (*Sir J. Thwaites.*) You start at an elevation of 212 feet and you give an inclination of 20 inches per mile; at what level would the water be when it arrived in London?—I propose to deliver the water that I bring down to the present water companies at Hampton for them to raise to high service reservoirs, and so gain the same service as the projects which have been laid before you would gain by gravitation.

1539. Then in point of fact you would employ mechanical means to lift the water in any case?—Exactly so.

1540. And to distribute it to any part of the metropolis?—By such means it would be distributed I believe in a more economical way having regard to the first cost as well as to the mode of delivery. I believe that by raising the water delivered at Hampton to different parts of the metropolis at the required height for the localities surrounding them you would do it equally well, and more economically than by bringing water either from Wales or from Cumberland to a height varying from 250 to 270 feet and from those points to connect the water with the service of the metropolis.

1541. We first want to get the facts of and then the comparison between the two schemes, what in point of fact would be about the level of your water supply?—It would be at Hampton from 10 to 20 feet above Trinity datum.

1542. Have you calculated the height that you would have to raise the water so as to command the houses in the higher parts of the metropolis to give a sufficient pressure?—A contour map of the metropolis would show you the parts of the metropolis which would be served at different heights.

1543. What is the highest?—To place the companies' services at Hampton in the same position as the delivery from Cumberland or Wales, that is from 250 to 270 feet above datum, the water would necessarily have to be raised by steam power from Hampton

on the west, or from Old Ford on the east of London to the height of 250 or 270 feet.

1544. Is 200 feet your highest point?—No. It is a mere question of power to what height you would raise the water, but there is a very large proportion of the metropolis which is under 100 feet. In the proposal I am about explaining I have gone into the question simply to show, as I can incontrovertibly, that there is capability of supply within the Thames basin, if storage be resorted to.

1545. (*Chairman.*) For the moment, going back to the gathering ground where you propose to start from and without reference to the height at which you would require to deliver it in London, what capabilities are there in that district in your view for collecting and storing water, Lechlade being as you have told us your highest point?—I gave Lechlade because it was the head of the conduit which would collect the waters from the higher grounds of the Thames basin.

1546. (*Col. Harness.*) Is Lechlade the outfall of your gathering ground?—It is the highest outfall of the gathering ground, which is coextensive with the Thames basin itself, reduced only by the height necessary for collection. I propose to make each tributary stream a means of bringing from the drainage area of that stream its quota of supply to a main channel, which main channel will start from Lechlade and deliver its waters so far as the west side of London goes to the several water companies works at or near Hampton, and to place that water upon the same level as the projects from Wales and from Cumberland, the water having been brought down to Hampton will have to be lifted by steam power to the various heights required for the districts in the metropolis.

1547. Leaving for a moment the question of lifting, I want to get first of all the ground where you would collect the water, the quantity of water that you would get, and the rainfall in that district?—I should be very glad to give that information. It is my object in coming here to lay those facts before the Commission. Why I touched upon drainage was, that drainage itself is a means of increasing the supply of water and we cannot exclude it from consideration. But to give some proof that there is water sufficient, I would just mention these facts to the Commission. The area of the water-shed of the Thames is 3,300,000 acres, the population we may take at 4,500,000, the average rainfall is 26 inches, the minimum is between 19 and 20 inches, and that minimum is disposed of in this way—3 inches support the perennial supply of the river, that is to say, maintain the river in summer at the ordinary height; taking 3 inches from 20 there remains 17, and of that 17 we find by information of various sorts that a very large share runs off to the sea in winter; but, beyond the fact that this accretion occurs when the rivers are full, there is another fact that whatever water is taken by under-drainage from the atmosphere it is so much positive increase to the river supply and as underdrainage proceeds so will the supply be increased.

1548. (*Sir J. Thwaites.*) Is that really so?—It is distinctly so, whatever is taken from the atmosphere goes to increase the supply to the rivers.

1549. My question had reference to the rainfall which finds it way into the earth, and which you drain off by means of pipes, and you allege that there is an additional flow into the rivers of that quantity of water?—I do not say that the whole is additional.

1550. Supposing it were not drained off and that the basin were full would not the rainfall upon it be absorbed or find its way off instead of being carried by your pipes?—The water falling upon a drained surface is absorbed by it and passes down to the drains and passes out by drains to the rivers. If the land were not drained the water would rest upon the surface and when that land was perfectly saturated the water would flow off the surface into the rivers, but a large quantity would be retained to be evaporated. Whatever diminution of evaporation takes place by drainage that quantity must go to increase the rivers. Experiments which have been rather largely carried out show that from clay lands 3 inches of rainfall is discharged while from a free soil which before drainage had been a sponge to hold the rainfall there is thrown off from 3 to 5 inches. I do not say that the whole of that is new water, but whatever proportion is rescued from the atmosphere and discharged by the drains must be new water; and the great fact bearing upon this inquiry is this that that discharge from the drains is all in the winter months. I am now speaking of clay lands, the discharge from free soils goes on very often through the summer. I have often adopted the practice when draining the clays overlying the oolite and chalk of digging holes or wells, called swallow-holes, and dropping the water of drainage down into these water-bearing strata, and the springs have been strengthened by the process. We originate springs by drainage of free soils; land that has never emitted water before is found to emit a constant flow of water from drains where the drainage is in free soils, but that is not so in clays. In draining clays the whole discharge is between the months of November and May. Now as that is discharged out of the ground into the valleys in winter it comes to the Thames when it is not wanted; and what I contend is this, that whatever water is thus thrown out by drainage from the upper marginal part of the Thames basin is capable of storage for supply to London. The quality of drainage water is sometimes objected to, but as I propose to use the stored water of winter as compensation to the river system for water taken out of the tributaries this objection has no force. Every inch of rainfall discharged from an acre of land yields 22,622 gallons, and as each person taking 30 gallons a day requires for the year 10,950 gallons, it follows that each acre discharging 3 inches of rainfall will satisfy at least 6 persons.

1551. Can that be additional water; is it not the case that that water is due to the rainfall to begin with?—Most distinctly so.

1552. Then that which you drain off is simply that which is absorbed by the soil and carried off by means of pipes?—Yes, exactly.

1553. But supposing there were no means of drainage at all and the basin were full would not that water find its way off in another form minus the amount of evaporation?—It would find its way off in several ways. When the land is perfectly saturated a part would flow off the surface, a very small proportion would ooze laterally through the ground into the rivers, and the rest would be evaporated and the water that would be added to the supply from drainage would be simply that which would be taken from the atmosphere by the reduction of evaporation.

1554. Then all the additional water that you are catching by means of your drainage is simply that which is not evaporated by being left on the surface; that is to say, all that you catch of additional water is that which you save from evaporation?—Exactly so, that is all. But let that be as it may, all the water that is discharged from drainage and from the surface of the ground by the improved system of outfalls which is taking place throughout the whole country being thrown down into the valleys in winter when the rivers are full, instead of being retained on the surface and in the ground for summer discharge, is capable of storage, and if the quality of the water be not that which is directly serviceable for supply, it can then be used for compensation to the river in summer.

1555. (*Chairman.*) The area you have given us in acres; could you denote it in any way by the names of places? Where would be the extreme point on the west or east?—The area that would be tributary to storage would be about half the watershed, and there are something like 3,300,000 acres which constitute the basin of the Thames.

1556. From what I understand you to say you propose to bring water from the north part of the basin?—No, I do not say that. I take the upper half

B. Denton, Esq.

7 March 1867.

of the whole basin of the Thames which contains 3,300,000 acres.

1557. From what part of that district do you propose to bring the water?—I propose to collect the water from the higher portions of the basin, that is from the oolitic sources on the north of the Thames, say from Cricklade to Oxford, and from the various streams rising in the chalk throughout the whole of the area of 3,300,000 acres. It is not possible to state the quantity of water discharged by springs from the water-bearing strata of the Thames basin, but it is pretty accurately known that, while 1½ inches of rain maintains the ordinary summer flow in the river from April to September inclusive, at least 4 inches runs off during the remaining six months from October to March inclusive, without taking into consideration excessive floods. The ordinary winter flow, in fact, compared with the ordinary summer flow is as 2½ to 1. No dogmas as to loss by evaporation and other causes touch this fact, which manifestly proves, when the discharged drainage water is taken into account, the capability of storing in winter all that can possibly be required for compensation in summer. I may here remark that, in considering the annual rainfall as an index of supply, a great mistake is often made owing to the fact that all published records give the quantity of rain that has fallen from the 1st of January to the 31st of December, thus cutting two winters in half. The meteorological year, in its influence on water supply, should commence at Michaelmas in the one year and end at the same period the following year, so as to include the whole of one winter and the following summer. It is the winter's rainfall that governs the summer supply. A close examination of the Thames basin will, I believe, show that the minimum quantity of winter's rain that has ever fallen between the 1st October and the end of March has been sufficient to maintain the proportion which I have stated.

1558. In point of fact you propose to collect your water from the whole of the Thames basin?—No, the height would not allow of that, but the proportion of the 3,300,000 acres out of which I think it might be collected is 1,500,000 acres.

1559. Will you first state distinctly the exact names of the places where you take your water from and then tell us whether you are of opinion that the water from your gathering area would be suitable for domestic purposes, having regard to the amount of cultivation and other polluting causes?—Your Grace has rather anticipated the description which I propose to give of the works, it was my intention to explain to the Commission, but answering your question in the best way I can I must say that it is not possible, as each tributary of the Thames will be a means of collection to particularize any parts. I can give you the names of the streams which would be made tributary, beginning with the Thames proper, we should then take the river Churn, the river Colne, the river Leach, and so on.

1560. Could you put in a plan with the districts from which you propose to take the water marked with any particular colour?—I have a plan which I brought with me, in order to illustrate my views in the clearest way (*producing the same. See Appendix V.*)

1561. (*Sir J. Thwaites.*) What we want to know is not the acreage of the water-shed of the Thames, in a large portion of which you could not collect your water at all, but you have your eye fixed no doubt upon some portion of that watershed from which you do expect to collect water?—Yes. If you will allow me to describe my plan in consecutive order all those facts will appear. For instance, I propose that the head of my conduit supplying London from the west should be at Lechlade.

1562. What we want as a starting point is, what area do you propose to utilize as the gathering ground of the water which you intend to bring to London?—All above the main trunk of the Thames.

1563. What acreage might that be?—I consider that the contributing space will be 1,500,000 acres, that is about 750,000 acres in the Upper Thames region, and 750,000 acres in the several other contributory areas.

1564. What is the condition of that 1,500,000 acres eliminating that from the other parts of the valley of the Thames?—The condition of that ground, speaking geologically, and looking to the furthermost northern part, is the great oolite formation. Looking to the other tributaries which do not rise from the oolite formation, you have the Kennet, you have the Colne, the Lee, and its various branches, all of which would be put under contribution, as I shall hope to explain to you.

1565. What is the surface condition of that district?—It is cultivated; highly cultivated in many parts.

1566. And of course subject to manuring and other processes?—Yes, it is.

1567. Can you suppose that from an area under the influence of that source of pollution you can get a supply of pure water for the metropolis?—Decidedly, because I propose to utilize for supply the waters which are collected by springs into the various tributaries which I have referred to, and which under proper conservancy may be perfectly purified, and kept so.

1568. I understand you that you have regard to the rainfall due from any area, amounting to 1,500,000 acres; but now you direct my attention to certain springs from which you propose to take your supply?—I propose to take the required quantity of water from various tributaries of the Thames, adding to their number as the demand for water increases, and compensating those tributaries for the water taken out of them by the collection of the surplus water from the surface.

1569. Do I rightly understand your answer to be this, that the primary source of supply is the springs?—The rivers themselves.

1570. The rivers themselves as the result of springs?—Yes.

1571. And the means of compensating those rivers will be the collection and storing of the rain-water?—Of the rain and drain water, the rain-water which swells the river principally, and the water that is brought down by drainage which is rain-water in another shape.

1572. In point of fact it is not part of your proposal to collect the rain-water due from that area, and bring it to London for the purpose of the inhabitants, but to intercept the streams that flow from the several springs that flow in that district?—I should take from each tributary as much water as those tributaries could supply, returning to them an equal quantity of water stored during winter.

1573. But are not those streams to which you refer fed mainly by the rainfall?—They are fed in some measure by the rainfall passing over the surface, but in the largest part they are fed by springs, which consist of the rain-water that has percolated through the oolite on the west, and the chalk on the east, and having passed through a great depth of soil rises again in springs and thus feeds the rivers.

1574. (*Chairman.*) Are not those rivers which you propose to put under contribution for your scheme now being made use of in the same manner by the existing companies?—They are; but the water collected from those tributary rivers is brought down by the main trunk to Hampton, where it is abstracted, and in their way partakes of the pollution which the main trunk suffers under from the sewage of the different towns on its banks.

1575. The existing companies have certain rights and powers over the districts in which those rivers are, and from which they take their water; how much water do you contemplate bringing?—The existing companies now draw out of the Thames at Hampton 60,000,000 gallons per diem, and they have power to extend that quantity, I believe, from 60,000,000 to 100,000,000; I propose instead of taking

the water as they do out of the main trunk of the river at or near Hampton, to take it out above the influence of contamination.

1576. Still their right to take it exists?—Yes, their right to take it exists up to 100,000,000 gallons per diem, I believe.

1577. How much do you anticipate taking per diem?—I propose to collect at once on the west side of London the 100,000,000 gallons which they ultimately have the power of taking.

1578. You propose to take 100,000,000 gallons, and they have power to take 100,000,000 gallons; do you propose that their power should be repealed?—No, my proposal would be simply to serve them with pure water instead of impure water as they now get it.

1579. Then is your proposal to take 100,000,000 gallons higher up, and give it to the companies, instead of them doing it for themselves?—I should propose to collect the water of the upper streams, compensating those streams by the surplus water, and bringing that pure water when collected down to Hampton, delivering to them by a channel, partly covered and partly open, from Oxford to Hampton or almost wholly covered, and to deliver to them the maximum quantity that they have now the power of taking out of the Thames after it is polluted.

1580. Then in effect for the powers which they have at present you would, speaking shortly, substitute yourself or your scheme. They take now 60,000,000 gallons per day, and they have power to take 100,000,000 gallons, and you propose that instead of their taking 100,000,000 gallons in the manner in which they do now, you should take the water some hundred miles further off, and take it down to them at Hampton, and give it to them, so you would do that which they have the power to do now?—Yes, but I should serve them with that which they have not got now, that is pure water instead of impure.

1581. But supposing that they think that their mode of collecting it is a good mode, and that they object to having 100,000,000 gallons abstracted from their gathering ground until you could show that you had the power to get another 100,000,000, do you think that there would be enough for both?—No, I am proposing to be the medium of supply to the companies. I am proposing a scheme, in fact, by which the water companies can obtain a pure supply instead of an impure one, and a larger quantity of water without at all interfering with the river system.

1582. But that would necessitate a repeal of their existing Acts, would it not?—I have not considered that point.

1583. Without expressing an opinion as to whether it is right or wrong, it would be so necessarily, would it not, if they have the power now of getting 100,000,000 gallons, and you propose to supply 100,000,000 gallons to them?—I presume that the object of the present inquiry is to secure a better supply of water than is at present afforded to London, both in quantity and quality. If you will allow me, I hope to show that by supplementing the present supply with storage, you can get quantity, and by going to the upper regions of the different tributaries, and dealing with the question of pollution in the way which I shall hope to explain to you, you can secure quality. It is the failing in quantity, and the failing in quality, of the present water supply that I presume has originated this Commission.

1584. Putting it in this way—If the scheme which you are proposing to us now were carried, the water companies would not be able, would they, to exercise the powers which they have now under Act of Parliament?—Of course, if there was any company or any body to take up the project which I am now endeavouring to explain and supersede the companies, that would be so, but that is not my idea. It is to supply the existing companies with pure water

1585. Would not the effect of your scheme being carried out be that the existing companies could not enjoy the rights which they now have by their Acts?—I do not consider that the necessity for the enjoyment would cease.

1586. But the fact would be so, would it not?—I am not able to give an answer to that question. I am not evading the question, but I do not feel myself competent to give an answer.

1587. What do you suppose is the capability of the ground from which you propose to get the water—how many million gallons per day?—I have told you that I propose at once to collect 80,000,000 gallons, and to construct a conduit capable of delivering 100,000,000 gallons to the water companies at Hampton.

1588.—You propose to take 100,000,000 gallons, and the water companies have power to take another 100,000,000; do you think that the ground would be sufficiently large to produce 200,000,000 gallons per day?—The two things could not exist together—the one would supersede the other.

1589. (*Sir J. Thwaites.*) As I understand you, you constitute yourself a wholesale dealer, and you bring the water in volume from the upper part of the Thames to a point where it could be conveniently taken by the several water companies. Supposing when you had got your water there the water companies were to say, "No doubt you are a very intelligent engineer, and have given yourself a great deal of "trouble and expense in bringing the water here, but "we prefer to take it from this point in the Thames, "we have authority to take it, and we can, by a system "of filtration, produce good and proper water with "which to supply the metropolis," how do you get rid of their powers and rights?—If the public were satisfied with that, and the companies could do what you say they might propose to do, there would be no necessity for a scheme; but I am assuming, and I think upon good data, that they are incapable of saying so, or doing so. If the result of the present inquiry should be that the water companies are prevented from taking water out of the Thames when its volume at the place of abstraction has been reduced below a certain fixed height unless they give back an equal quantity, and they are further prevented from taking water out of the river into which the sewage of any towns above has been in any shape discharged when the quality does not come up to a fixed chemical standard, then there would be no further complaint on the part of the public. The companies would then necessarily resort to storage for compensation, and would thus maintain the standard volume through the metropolis, and they would ascend the river for the water of required purity should analysis show the supply to be defective in quality.

1590. Is it any part of your scheme to deal with those companies, because, if they do not take the water of you when you bring your water to that point, unless you yourself have a system of distribution to the metropolis independent of the water companies, the water would be of no value?—Exactly so. My scheme really consists in utilizing the upper streams of the Thames—not only those that rise in the oolite to which we have given the most of our attention, but those on the east, from the chalk, and those on the south from the Greens and Bagshot sand—utilizing those streams by taking pure water out of them, and returning to them an equal amount of collected surplus water. I am not prepared to do more than to show that there is a full sufficiency of water in the Thames basin, and that the quality may be, by proper conservancy, made so pure as to be equal, or nearly equal, to that which can be obtained from Wales or Cumberland.

1591. (*Sir B. Phillips.*) Do you propose to give to the water companies 100,000,000 gallons of pure water in lieu of 100,000,000 gallons of the impure water that they now deliver, or do you propose to give that as an addition, making together 200,000,000 gallons?—I propose to deliver 100,000,000 gallons to the water companies on the west, but I also propose to deal with the New River and the East London in a way that I should like to make plain to the Commissioners. There

B. Denton, Esq.

7 March 1867.

is a very large quantity of water to be gained from the chalk on the east as also there is from the oolite on the west. In addition to the streams from the Upper Thames and the Lea, there are, as the Commission are aware, the Kennet, the Coln, the Wandle, the Mole, the Wey, and various other streams, all of which may be put under contribution as the demand for water increases.

1592. It has been stated to the Commissioners that it would be of no use to entertain any scheme which would not deliver to London from 200,000,000 to 250,000,000 gallons per diem; how could you meet such a large demand?—If I am permitted I can show that the Thames basin is quite capable of doing that, but I would start by delivering 80,000,000 gallons to the companies taking their water supply from Hampton, and 40,000,000 to the New River and the East London, and the simple way in which I propose to do that is as I have stated before by utilizing the upper streams of the Thames and the Lea and repaying those streams by collecting the winter's surplus water.

1593. There are two conditions which it would be necessary to fulfil, first that the water should be pure, and secondly that it should be soft; would you deliver water both pure and soft?—There is a great deal to be said upon the question of softness which I do not think has yet been considered. I admit that a vulnerable point in the project which I place before the Commissioners is that the water will still be comparatively hard, but that the hardness of the Thames water will be greatly reduced by carrying out the principles which I have partly enunciated and which I wish further to explain is equally certain.

1594. (*Chairman.*) You have stated to the Commission that you propose to collect the water somewhere near Lechlade over an area of 1,500,000 acres will you tell us how you propose to take it?—At Lechlade the Thames and Severn canal joins the Thames, and higher up the North Wiltshire canal joins the Thames and Severn canal. I propose to purchase those canals and utilize them for the collection of the waters of the Thames above. Then passing down from Lechlade I propose to collect the waters from the various tributaries, the Coln, the Leach, the Windrush, the Evenlode, the Cherwell, and the Ray, making a concentrating reservoir just below Oxford.

1595. What would be the size of that reservoir?—That reservoir would not be a large one, it is to be only a mere concentrating basin.

1596. But what would be the size of it?—That has not been determined. In fact it is not necessary to refer to it at all as it is not a feature in the scheme. Then passing down from Oxford to London, the Ock would be in the same way brought under contribution, and the Thame, the Loddon, and the Coln. The points where I should propose to have my compensating reservoirs would be those that occur at the junction of the impervious bed of the Oxford clay with the oolite,—in point of fact that is the lowest point from whence these springs are emitted from the water-bearing strata of the oolite—and by having my compensating reservoirs there, I should be enabled to utilize and bring down the whole of the water required from the various streams into my collecting conduit.

1597. What size would that conduit be?—That conduit would vary in size telescopically as it would collect water from the various tributaries.

1598. How do you get the water into it?—The water from the upper portions of each stream would be brought down by a channel devoted to the purpose above the surface of the ground of the main valley, so that no flood water or polluted water could enter. Those channels would follow as near as practicable the lower courses of the tributaries, and would be in size apportioned to the quantity of water to be taken from each stream.

1599. Can you give us all these matters in detail?—I can explain it to you now; I am not prepared with any detailed estimate.

1600. Could you tell us what would be the quantity of water and what would be the size of the conduit?—The several quantities contributed by the tributaries I cannot tell you, as there is a total absence of gaugings of those streams. We only know at certain point upon the main trunk, after those various tributaries are collected, the quantity of water that passes down the Thames; that is all we do know; there is a total absence of reliable gaugings.

1601. (*Mr. Harrison.*) You would pass your conduit, would you not, above the level of all those streams at the point of crossing?—Yes.

1602. And that would give a sufficient fall so as to put the pipe across and bring the water into your conduit?—Yes. I should like to explain, if the Commission have sufficiently followed me and I have made myself intelligible, that on that plan which I have produced, the margin of the yellow gives the line of demarcation between the water-bearing stratum at its outcrop and junction with the Oxford clay. From that line to the main trunk the tributaries are mere conduits for the water which has been collected above, and I should propose to have my reservoir on each as near as possible to the junction of the two strata, taking pains by intercepting the sewage above to keep the streams as pure as possible, in perfect purity I would say, and making a reservoir there to hold the surplus water brought down in times of excess in order to repay the quantity of water taken out above. The whole surface of the country above the line of demarcation I have described, having absorbed the rain which maintains the springs, is obviously capable of absorbing any amount of sewage that may be utilized on its surface. If the Conservators of the Thames would compel the application of the sewage of towns above the line of demarcation to high grounds of a porous character, where it would act as the water of drainage, when dropped into swallow-holes, to increase the volume of the springs, the difficulty would cease, and such a plan must be preferable to irrigation on low meadow ground, where the effluent water, passing *over* instead of *through* soil, must always be charged with a certain proportion of sewage in solution, if not also in suspension. A study of the geological character of the upper portions of the Thames basin—the chalk and the oolite—will satisfy you that, maintaining as they do the river system of the Thames, they are capable of absorbing sewage to any amount, with benefit rather than injury to the springs themselves.

1603. (*Chairman.*) How do you propose to intercept the sewage?—I propose to intercept the sewage in two ways; for a certain distance up each contributing stream it would be by intercepting open drains; above that, and wherever, in point of fact, it would be more economical to do so, I propose, by compulsory powers over the towns and villages, to raise the sewage on to the hills so that there should be a complete absorption of the sewage into the soil.

1604. When you speak of by compulsory powers over the towns and villages, what description of powers do you propose to obtain?—The power to exclude sewage will exist, I believe, in two years from this time for the main trunk of the Thames. No town will be allowed after a certain date (I do not know the exact date) to discharge its sewage into the Thames; they must find some means of dealing with it other than the system now adopted, and I would suggest that the compulsory powers should be extended to the tributaries.

1605. What would you propose to do with the sewage?—To use it for irrigation above, though the mode of application would be different.

1606. How would you get at it, and what would you do with it?—The plan which I should propose to adopt for the higher towns would be that which is being carried out at Watford and Rugby, and in various towns and places where lifting is adopted. Where it would be conformable to the system which I am now explaining the sewage from the towns would be carried down to the meadows below by gravitation, and then thrown over the land, and the drainage of the irrigated lands passed down by an open channel to a point below the point from which we should take our water supply.

1607. (*Sir J. Thwaites.*) Where would be your point of discharge, because you are aware that you could not apply the sewage at all times of the year to the land, at times of cropping, for example, and in frost and snow, and there are a variety of conditions which would be a bar to your applying it to the soil?—That is an objection which has been often raised, but it is removed by the towns taking upon themselves a certain quantity of land, we will say one acre to every 100 inhabitants, and arranging the land in pasture and arable cultivation, by which plan the whole of the sewage may be applied all the year round.

1608. Supposing that you had six weeks of frost in the winter, what would you do with your sewage; you could not apply a gallon to the land in that condition, but there could be no stop to the flow of the sewage?—That could only occur in extreme cases, for by the diversion of the contributing streams in the way that I am speaking of you would do no injury to the water to be utilized for the supply of London if the discharge from the irrigated grounds or the sewage in its worst state were discharged below the point from whence you take the water.

1609. (*Mr. Harrison.*) Take such a case as Banbury, which is to be your northernmost point, how would you avoid the sewage from that place polluting some of the streams which would come into your conduit?—I should propose to exercise compulsory powers to oblige the town of Banbury to raise the sewage water to lands much above the river.

1610. Still the water from those high lands would drain down into the river, would they not?—It would if it were not intercepted by swallow-holes, which would at all times afford a simple remedy.

1611. (*Chairman.*) During part of the summer when the crops are coming up, would you not ruin the crops by covering them with sewage?—By using the sewage for grass land that would not happen, because you would continue to mow the grass green and have fresh land upon which to apply the sewage.

1612. Do you mean to make the corporate body of the town a sort of farmer?—That is the provision now made by Act of Parliament, every town in England will sooner or later be obliged to make such an arrangement as that. They must either lease the land or buy the land, or dispose of their sewage to the farmers to lift or gravitate.

1613. (*Mr. Harrison.*) Do you think that you could effectually prevent any sewage after being so used from coming into those streams?—I have given that point considerable attention. Going to the river Lee as an instance, which I should like to deal with particularly, I would put as a parallel to Banbury the town of Luton, which lies at the head of the river Lee, or nearly so. I should require that town to lift its sewage on to the hills above it, if they are chalk. There is a very mixed character of soil in the neighbourhood of Luton and the sewage might be lifted there 100 or 150 feet and put upon land which would absorb it. And then answering your question, I believe that by the percolation of that sewage through the 100 feet or more which it must pass through to get to the river, a perfect purification would take place.

1614. Does the Act of last session give power to compel parties to lift their sewage 150 feet?—No, I do not know that it does. I think that irrigation by gravitation was the principle most in view, but it must be extended if the required purification cannot be attained without lifting.

1615. But as it exists now any compulsory powers under that Act would be simply this, that you would use the sewage, and the water would then again come into the Thames?—I do not think that the Act prescribes the mode of application.

1616. I mean, that there is no compulsory power to compel them to lift their sewage to any given height?—Perhaps not; but the prohibition, if strictly exercised, would be sufficient of itself. No town could then discharge its sewage into a river in an impure condition, that is to say, it must undergo such a purification by irrigation or otherwise that the liquid remaining shall go into the river in a pure state.

1617. (*Sir J. Thwaites.*) Would the waters from the land so irrigated flow into your source of supply?—I propose that on the higher portion of these streams all the towns should be obliged to lift their sewage if the water cannot be purified, as I believe is the case, by irrigation at a low level. The difference of the effect in lifting the sewage and letting it pass by gravitation would be this, that the sewage would be lifted in the first case on to a high surface of porous ground which would absorb the sewage, and the depth between the surface of the ground to which it would be applied and the river would secure perfect purification; while in the second the effluent liquid after irrigation would pass into the river immediately.

1618. Have you examined the sewage water as it passes off after it has been used for irrigating purposes?—It would not be possible to distinguish the water that would pass through 100 feet of soil from that water which would rise in the ordinary nature of a spring.

1619. Have you examined the application of the sewage at Croydon?—I have not examined the application of the sewage at Croydon, but at Rugby I have, and in most of the instances where it has been applied.

1620. Although the water may run off completely, it does hold in solution, does it not, a good deal of matter which would be most offensive?—There is no doubt about that, where the sewage passes only over the surface, but it would be totally different if it passed through a porous stratum 100 feet deep.

1621. Notwithstanding your application of the sewage to the adjoining lands of the several towns on the rivers in order to prevent its flowing into and so contaminating the streams from whence you take your supply, will not the water find its way into your streams after it has done its duty in irrigating that land?—Yes, where it is applied by gravitation to riverside meadows or impervious soils, but I wish to be understood that I should propose to intercept all sewage water, whether it has been used for irrigation or not, and to discharge it below the point from whence I would take my supply.

1622. Then any water due from the area under irrigation would not find its way into your channel?—Not into that part of the river which would be utilized for supply.

1623. Have you made a section of your culvert or aqueduct by which you propose to bring your water the 127 miles?—The valley itself is the section.

1624. You propose, therefore, to bring this water in a given channel, and to exclude any source of contamination?—Yes, I do.

1625. In order to arrive at an estimate you have calculated, no doubt, the size of the aqueduct which would be necessary to bring the volume of water that you require for the supply of the metropolis?—Yes, I have.

1626. At what size do you begin?—The conduit from Oxford to Hampton would, in the same way as I have explained with regard to the upper conduit, gradually increase as contributions were made from the streams crossed between these points, which include the Ock, the Thames, the Kennet, and the Colne. The Wey and the Mole would have a separate system and would be added when the demand increased. They are capable, if the Bagshot sand district be added, of supplying from 30,000,000 to 40,000,000 of gallons daily.

1627. You would increase the capacity as you go along, but what do you start with?—It would be partly open and partly covered. Where it was eligible to have an open channel, it being cheaper, I would adopt it, and the size of that open conduit would be 12 feet 6 across, with a depth of 6 feet, and where covered it would be eight and a half feet circular.

1628. And you give to that, do you not, a fall of 20 inches to the mile?—Yes.

1629. That would render necessary a lining to the aqueduct, would it not?—Yes, it would.

1630. Of what material do you propose to line it?—

B. Denton, Esq.

7 March 1867.

Partly of concrete and partly of brick is what I have proposed.

1631. What proportion of the 127 miles is in tunnel?—About half the 90 miles from Oxford to London would be covered, and the part above Oxford would all be open.

1632. (*Col. Harness.*) When you speak of the other part being covered, you do not mean, do you, that it is to be in tunnel?—Approximating the surface. The sides of the open channel would be sufficiently above the surface to exclude the floods.

1633. (*Sir J. Thwaites.*) You merely cover it for surface convenience; it is not as if you were passing through a mountain?—No, I propose to cover it simply to keep out the pollution of the atmosphere.

1634. Of what size are your compensating reservoirs in the upper part of your gathering grounds?—The size of those reservoirs would be various, and they would agree with the quantity of water extracted from the several tributaries. Upon the whole, I consider that we should require on the west of London, that is to say, for the Thames, 2,720 acres of water surface, with 280 acres for banks to enclose the reservoirs, making together 3,000 acres.

1635. I presume that those reservoirs would be formed in convenient valleys?—They would specially be constructed on clay bottoms in the valleys, not in the way which is adopted in the higher hilly and mountainous districts of England; they would be formed on the flat, if I may use the expression; they would be entirely embanked by made banks, which I contend would be not only safer to retain the water, but less dangerous to the people below, being less in height. The height which I should propose to have the water in the reservoirs would be 20 feet—that is, from four to five feet under ground, and the remainder above, the depth below the surface being according to the depth of the streams to which those reservoirs would be addenda.

1636. Do you concrete the bottom of those reservoirs?—No, I have not proposed to do so. You observe that they would be compensating reservoirs, and would not be required for supply; the supply would be taken from the streams above.

1637. My question had merely reference to their capacity to hold water?—They would be made upon impervious soil.

1638. What would be the total expense of the formation of your reservoirs and of the conduit up to Hampton, giving a capacity equal to supply 100,000,000 gallons per diem?—I do not propose to make the reservoirs for 100,000,000 gallons on the western side at present. I propose to make the conduit sufficiently large to bring down 100,000,000 gallons, but the reservoirs, which would only hold six months' supply of 80,000,000 gallons daily in the first instance, would be increased in size and number as the supply was required to be increased. The cost of the reservoirs of which I have now given the figures, making, in the whole, 3,000 acres, would be 1,360,000*l.*

1639. Do you mean that 1,360,000*l.* will cover all your structural cost, including the price of 3,000 acres of land, and the compensation payable in respect of severance and easement, and so on, up to Hampton?—I am dealing now simply with the reservoirs, which would be in blocks, and there would be very little consideration due to severance.

1640. I want to know the total cost of your scheme, including such reservoirs as may be necessary to compensate the rivers for the water abstracted, the formation of your culvert, the cost of the land which you must purchase for that object, the easements, the severance, and all structural cost up to Hampton?—In my published paper I gave the total cost at 4,500,000*l.* I have increased that, because I have increased the size of the conduit from the 80,000,000 gallons capacity to 100,000,000 in the case of the Thames, and correspondingly on the Lee. I have increased that cost from 4,500,000*l.* to 5,320,000*l.*

1641. If I understand you rightly, then, this is only a part of a general scheme for the supply of water to the metropolis. Do you propose to deal with the New River?—I propose to supply the New River with pure water.

1642. But not from this source?—No, not from this source, but from the upper part of the Lee.

1643. You say that 4,500,000*l.* is to be the expense of this scheme?—No, it is the expense of the whole to supply immediately 120,000,000 gallons, with the capability of increasing the supply up to 160,000,000.

1644. You do not mean, do you, that the structural works would have a capacity given them to supply up to 160,000,000 gallons, but that 4,500,000*l.* is the expense which you would incur to supply 120,000,000 gallons?—Yes, with capacity in the conduits for the larger quantity.

1645. Then it is simply increasing the reservoir accommodation?—Exactly so, the only addition that would be necessary, would be to increase the size or multiply the number of the reservoirs.

1646. You increase that 4,500,000*l.* by what sum?—I have already increased the estimate to 5,320,000*l.*; the only additional cost to secure 160,000,000 gallons daily would be in the reservoirs.

1647. Then that brings the water near to London?—It brings to the works of the different companies the quantity of water that I have mentioned.

1648. I understand that that expense leaves us at the mouth of the tunnel; there is no resevoir at Hampton, and no head by which you could supply it to London, and that must be a separate expenditure, must it not?—Precisely so. The companies now raise the supply, and they will be obliged before long to furnish it at constant high pressure. I see that Mr. Bateman estimated the cost of lifting and filtering the present supply of water at 75,000*l.* a year.

1649. There is no filtering included in the present proposal?—No, he incidentally in his pamphlet stated that the present cost to the companies of filtering and raising the water was 75,000*l.*, I would increase that to 100,000*l.*, and of course if you multiply that by 20 years' purchase, it represents 2,000,000*l.* of capital.

1650. That is the cost of the pumping power necessary for the present supply?—Yes, 75,000*l.* is, and increased as I would increase it, it would be 100,000*l.*

1651. Would that give the quantity of water necessary for the supply of the metropolis for the next 10 or 20 years?—Probably not for the next 20 years, but it would be equal to supply 120,000,000 gallons daily, the present supply being 100,000,000 gallons. My proposal embraces three sources of supply with a means of future augmentation, viz., the upper sources of the Thames giving 100,000,000 daily, the Lee giving 60,000,000, the Wey and the Mole giving 40,000,000, making 200,000,000 daily, exclusive of the Colne and the Wandle, which with storage may provide a share at some future time.

1652. (*Col. Harness.*) Have you at all pitched upon the sites at which you would make your reservoirs?—Not definitely.

1653. (*Mr. Prestwich.*) You say, do you not, that at Lechlade the height of the reservoir would be 220 feet above the Thames at London?—Yes.

1654. Would it not be possible then to bring that water and deliver it in London by gravitation, following the course of the Thames valley?—No, it would of course at a certain cost be competent to bring the water and deliver it at a higher point than we now propose to do. If we started from Lechlade with a descending contour line catching the tributaries at the highest available points, the collected water might be delivered, perhaps, at 100 feet above ordnance datum; if we started from Cricklade, perhaps, at 140 feet; if we went higher still and could gain all that is wanted by pumping at Thames Head, we could deliver the water 150 feet above datum, but this is not likely.

1655. But independently of your own plan, could that water be brought a distance of 100 miles, and delivered in London at a height of a hundred feet?—Yes.

1656. (*Col. Harness.*) Of the 120,000,000 gallons, what proportion is receivable at Lechlade?—A very

small quantity; the least quantity would be there, because that would be the head of the system.

1657. You have not stated in figures, have you, what would be the proportion?—No, I am not prepared to state that.

1658. (*Mr. Prestwich.*) Could you give us some particulars with regard to the springs which supply those tributaries, and the quantity in the different valleys?—At present they are pumping 3,000,000 gallons daily out of the oolite into the Thames and Severn canal, of which the greater portion finds its way into the Severn, and not into the Thames, and one of my reasons for suggesting the purchase of the Thames and Severn canal was that that 3,000,000 gallons should be the first contribution to London, which would in fact be a restoration of the Thames basin to that extent.

1659. (*Chairman.*) How does that water find its way into the Severn now?—It is pumped out of the oolite by the Thames and Severn Canal Company into the canal, and is used for canal purposes towards the Severn.

1660. What would the Thames and Severn Canal Company say to your proposal?—It would be part of the project which I have laid before you to purchase the Thames and Seven canal. This water is pumped up to the summit of the Thames and Severn canal.

1661. Does the Thames and Severn Canal Company carry on any business?—It does, but as was mentioned in Parliament last year, it is in such a state that a small amount of money might purchase it.

1662. (*Mr. Prestwich.*) Do you know the quantity of water that flows down the Thames at Lechlade?—I do not. I have already observed that there is almost a total absence of any reliable gauging of the Thames and its tributaries, but we do know this from the evidence of Mr. Stacey before the Rivers Commission, and a remarkable fact it is, that the general summer average volume at Wolvercot, which is just above Oxford, is 73,000,000 gallons *per diem;* but in the dry summer 1865, it was reduced down to 62,000,000 gallons. But the winter flow is represented by very different figures. On the 2nd of January 1863 the quantity flowing down was 321,000,000 gallons, which is represented as the ordinary winter flow; it increased gradually in five days to 350,000,000, 430,000,000, 588,000,000, 636,000,000, 702,000,000, and 742,000,000, which was the highest it arrived at. I submit that that must go some way to prove the capacity of the Thames basin to supply water if the surplus be stored in winter, to compensate the rivers for what may be taken out of them in summer. It will be observed that Mr. Stacey represents the ordinary winter flow at Wolvercot as about $4\frac{1}{2}$ the ordinary summer flow instead of $2\frac{1}{2}$ times as I prefer to take it.

1663. Have you formed any idea of the quantity of water that you would get from the tributaries above Lechlade?—I have not, but there is a fact which is known to most engineers, and the Honourable Commissioner will perhaps be able to appreciate it better than I can, that 3,000,000 gallons are lost out of the Churn in a passage I think of five miles when passing over the oolite, and that quantity is not recovered again.

1664. You have noticed have you not, that in many cases where the springs rise in the higher tributaries as they pass over permeable beds, the stream loses a portion of its volume?—That is the case with the Churn. The Churn was gauged very accurately by Mr. Simpson or his assistant, and the quantity of water at one point was found to be lessened a few miles further down to the extent of 3,000,000 gallons.

1665. You would therefore place your collecting reservoirs above the points where the stream passes over permeable strata?—No, my object would be to collect the water that comes out by springs from the pervious strata at their junction with the impervious.

1666. Would each tributary have its separate reservoir, or should you have one common reservoir lower down in the neighbourhood of Lechlade?—I propose at present to have one reservoir for each tributary, but if it were cheaper to connect the tributaries than to have one reservoir for each tributary, that would be the better plan to adopt.

1667. Would you have in this district between Cirencester and Banbury a series of reservoirs near the head of the tributaries?—No, not near the head of the tributaries; it would be so far down each tributary as would correspond with the junction of the porous with the non-porous strata, as nearly as possible conformably with the line of outcrop which is marked on the map. Of course in carrying it into practice that line would not be strictly followed, but that serves to put the matter before you.

1668. That line of outcrop would represent a line some feet above the reservoir at Lechlade would it not?—It would be several feet above the junction at Lechlade.

1669. The ground would be higher also, I suppose?—Yes; the plan that would be carried out if this scheme were adopted would be this, that one or two mills as near as possible to the line of this outcrop on each of those streams would be purchased and the mill head would become, in point of fact, a reservoir from whence to take the water, and just below that mill head you would have your compensating reservoir.

1670. Can you give us some idea of the height above the Thames at London of the ground at the lines of junction?—It varies.

1671. You give us a height of 210 feet at Lechlade, this line is apparently above that height, is it not?—Here is a map (*producing the same*) which will make the matter much more clear. It is the geological map of the district, by which you will observe that the various tributaries which come down from the oolite run over the Oxford clay and join the main river in the Oxford clay (*describing the map to the Commissioners*). The line along just below Cirencester to Fairford, Witney, and Woodstock, and from thence to Bicester, marks the outcrop of the Oxford clay where it joins the porous oolite. I have been asked what fall there is from that line down to the main river, and I am afraid I cannot answer that question, but you will observe Lechlade on the map and two mills (*pointing out the same*), the last of which must be several feet above the river, and to that extent only can I answer the question.

1672. Still that would not take it beyond the limit of 250 feet?—No, it would not take it above 250 feet, and the distance being so considerable you could not look to any very great advantage by bringing the water by a contour line to the highest point at which it would fall by gravitation.

1673. All those springs above Lechlade arise in the oolites, do they not?—Yes.

1674. Have you had any analysis made of those waters?—No, I know pretty nearly that they show an extent of hardness of something like 13 or 14 points.

1675. They are waters which are rather harder probably than the waters of the chalk districts?—I think they assimilate very nearly. I should like very much to put before the Commissioners this section (*producing the same*) which shows what I am proposing to do on the river Lea. The point C represents Feilde's weir, which is 80 feet 3 inches above Trinity datum. All the water above that I propose to maintain clear by the interception of the sewage and lifting it in certain places, such as Luton and Bishop's Stortford, where I propose to lift the sewage on to the hills and let it pass through the soil before it reaches the river.

1676. (*Chairman.*) That is to say, you propose to compel the towns to lift the sewage?—Exactly so. They will in any case be compelled; in a few years it must be done. I will assume that by the exercise of compulsion to the extent which I have spoken of, certain towns should lift the sewage, and in other cases that they should discharge it by gravitation and run it over the land, and only discharge the refuse liquid after the service of irrigation into the river below Feilde's weir. By that means the water above Feilde's weir would be maintained in purity, and

B. Denton, Esq.

7 March 1867.

above that point the two water companies, the East London and the New River Companies, would take their supply. You will observe on this section that the water from above Feilde's weir may be conducted into a reservoir so far down the river as to allow of a depth of 20 feet. It is proposed there to collect 20,000,000 gallons per day, for 182 days and from thence to take it by a covered channel to London.

1677. What is the quantity which is proposed to be taken?—The East London and New River Company now draw 40,000,000 daily from the Lea, but the quantity of water stored in this reservoir is compensation for that which may be taken out above to the extent of 20,000,000 gallons per day for 182 days.

1678. (*Sir J. Thwaites.*) The sewage at Luton goes into the river Lea there, does it not?—Yes. Above Fielde's weir I propose that the sewage should be perfectly intercepted and applied on the hills by lifting or in the valleys by gravitation, so that by perfect purification the water may be taken for the supply of the east of London. Below that point all the sewage should be clarified by irrigation or by other chemical processes, and returned into the river, not for the purposes of drinking, but for the purposes of maintaining the navigation and supplying the mills below the point of abstraction.

1679. (*Col. Harness.*) Have you computed the extent of intercepting drains for sewage that you will have to construct for the whole of your scheme?—I am not proposing that any part of this mode of supplying London should deal with the question of intercepting the sewage. I consider that the towns themselves are already under obligation to intercept their own sewage; at any rate in two years from this time they will be compelled to do so.

1680. Would that be only as far as the main stream is concerned?—That only applies to the main stream.

1681. But you are taking the water from the tributaries, and therefore you must intercept the sewage running into the tributaries?—I believe there is a bill now before Parliament to extend the Conservancy of the Thames to its tributaries, and I assume that the powers which are now vested in the Conservancy Board for the main stream will be extended to the tributaries.

1682. (*Chairman.*) By whom is that bill promoted?—By the Government, I believe.

1683. Is there any other point in connexion with your scheme that you wish to put before the Commission?—I want particularly to impress upon the Commission this consideration, that in taking water from a distance, from one valley and applying it to another (take the Thames valley for instance), the onus of proving that the valley to be supplied is incapable of furnishing its own supply should rest with those who would supply it from a distance. I contend most positively that if the matter be fully examined the quantity of water within the Thames basin is more than ample to supply the requirements of the inhabitants. I admit that in point of hardness the water obtained from the primitive formations or from the transition formations of Wales and Cumberland is very superior, but upon the question of quantity there can be no doubt that the capabilities of the Thames basin are equal to any demand; and the point that I wish to speak of now is this, that the increase of population in the north in the manufacturing districts is so enormous that we ought not very hastily to bring water from the heights which surround those districts to another valley which is able to find its own supply. The increase of population in those manufacturing districts is enormous, and must in the course of a few years render the population of the Thames basin of very secondary importance.

1684. (*Sir J. Thwaites.*) Is it not rather a question of free trade, whether you have not a right to go to the best market for the article that you require unless you are robbing other towns?—I contend that you would most seriously rob other towns, besides disregarding existing interests.

1685. Take higher points, such as Wales or the lake district, which it is not at all probable will ever be occupied by a large population, must not these necessarily be gathering grounds for the supply of districts that may be insufficiently supplied, unless you can show that you are robbing other districts and taking water which is due to them?—I believe I can show that most perfectly. The population of the manufacturing districts at this time, taking the counties of Warwick, Worcester, Stafford, Chester, the West Riding of Yorkshire and Lancashire, is 6,000,000. The increase during the last 50 years in Lancashire has been threefold; it has increased from 800,000 to 2,400,000 and more, and taking the increase of the other counties one cannot suppose that the increase of that population would be less than double in 50 years. I am content to take 50 years, and 50 years is but a very small period for us to be assuming when considering the question of water supply.

1686. Supposing the population should be doubled, with your knowledge as a civil engineer, your attention being directed to these questions, are you not of opinion that the gathering ground either in Wales or in the lake district is sufficient for five times the population of that district?—I have very grave doubts upon that point, and doubts arising from a consideration of the subject, and an intimate knowledge of Wales, from having considerable works there. I believe most seriously that it is much easier for us to conserve in the Thames basin a small proportion of the rain collected from a larger area than it can be safe to rely upon a larger proportion of rainfall from a limited area.

1687. Would not it be competent to any one of those towns to obtain a supply of water from ground similarly dealt with in its surface to that which you propose here, namely, the cultivated districts in the upper part of the Thames basin, the high grounds in Derbyshire, and other places which are partially cultivated?—They would not have capacity; there is not the means at command. The whole population is requiring a supply, and Derbyshire is requiring it as well as the manufacturing district which outskirts that county.

1688. Why has not the metropolis, finding its need of a certain article, and that a pure article, a right to go to the very best place at which it can be supplied with that article?—For two very good reasons. The first is, that to take, as is proposed, a large body of water varying from 200,000,000 to 300,000,000 gallons per diem from a river like the Severn is likely so to alter the physical condition of the river itself, as to be very detrimental to it; but allowing that it must ultimately be taken for the manufacturing districts if it does not come to London, it is certainly very much better to apply that water to the use of the districts watered by the Severn, that is to say, to those districts which exist upon the new red sandstone, than to bring that water across the new red sandstone and away from those districts to the metropolis, as it is proposed to do. By retaining the water within the water-shed of the river, as it might be, and by applying that water to the manufacturing districts, which some day or other will require it, the river does not lose the water, but the water still remains, although polluted, for all the river purposes for which it is wanted; whereas if it is taken away from the river to London, the advantage of having that quantity of water in the river is lost.

1689. Would not the same reasoning apply to your scheme, that it would abstract a very large quantity of water from the Thames which you propose to compensate by means of reservoirs storing the rain-water?—I do not propose to take water out of the Thames basin.

1690. You propose to abstract it from the tributaries of the Thames, which is the same thing, and if the law of compensation were put in force either in Wales or in Westmoreland, surely the same result would follow; you would not damage the rivers there more than you would damage them here?—No, but the rivers are differently circumstanced. I believe that the Severn and all rivers rising in high grounds and flowing through the red sandstones, old and new, require a

larger quantity of water for flushing, and that floods are necessary to keep the channels of the river open. Over these formations the rivers pass by comparatively low gradients seaward, bringing down turbid waters from their sources. The surface beds of the old and new red sandstone are easily abrased, and if there be not frequently full bodies of water to scour their courses of detritus and river-side abrasions, they would soon become choked, and navigation would suffer. I have particularly observed this influence in North and South Italy, where the rivers from the Alps and Apennines pass over comparatively flat districts before reaching the sea. The fall of the Severn from the English stones near Kingroad, is 34 feet in 40½ miles, while from Gloucester to Worcester it is only 16 feet in 29 miles, and from Worcester to Stourport 17 feet in 12 miles. These observations do not apply in the same way to the Thames; but that is not the paramount point to which I should draw the attention of the Commission; it is to the requirements of the manufacturing districts for an increased supply. For instance, if the increase of population as I say will be in 50 years at least double, and instead of 6,000,000 there be 12,000,000, you would require at least that which is proposed to be brought to London from either Wales or Cumberland to supply the additional 6,000,000 of population which will be within the manufacturing districts.

1691. (*Sir B. Phillips.*) If I understand you rightly, you say that the Thames basin will supply a quantity sufficient for the purposes of London?—Yes, quite sufficient.

1692. But as to quality, I do not think that you express a strong opinion, or rather you say that the quality is not so good?—I say that the quality for drinking purposes is equally good, and that all the most healthy towns in England, and, in fact, throughout Europe, have hard water from calcareous strata. There are purposes which have been referred to by Professor Way to-day, for which the water of the Thames would not be so good, but with the power which we have of softening water by Clarke's process and by the power of chemistry, I assume that it is certainly easier to make hard water soft than to purify water, and by having recourse to Clarke's process or to any other process that objection might be overcome.

1693. A great element in the supply of water to the people of London would be the sanitary consideration; do you suppose that looking at it in that point of view the water supplied by the Thames basin would be quite as good for sanitary purposes as the water supplied to the lakes of Westmoreland and Cumberland?—I do not know any reason why it should not, the only disadvantage in the Thames water is its hardness, and that may be reduced, for we know very little indeed of what the effect of collecting water in large reservoirs will be. A little circumstance came before me, or rather was mentioned to me by Mr. Beardmore the other day with regard to a spring rising from the chalk which flows down by a watercourse into the Lea. It is part of his duty as engineer to the River Lea Commissioners to keep this watercourse clear; he has to empty it periodically of any sediment or any matter that may be in it, and he told me that the quantity of lime which was precipitated by the water in its passage from the spring where it rises to the Lea was very great indeed, and in fact that the matter which he had to remove from the watercourse consisted of lime which could only have been precipitated by the water in its transit from its source to the Lea. And I submit that we are not now in a condition to judge of what would be the softening effect of the collection of a large body of water in reservoirs as I am proposing it should be collected.

1694. Reverting to the sanitary uses of water, are you aware that during the rage of the cholera in the eastern parts of London last year, there were many eminent men who gave it as a positive opinion that in many of those districts the virulence of the disease was materially influenced by the bad character of the water which was supplied to the inhabitants?—I know that to be the case, but I know that the cause was the pollution of the stream, not the hardness of the water. I am assuming as the very basis of the project which I am laying before the Commission that the conservators do their duty, and pollution is prevented, that no water is taken from the streams until the sewage has been perfectly intercepted above the point of abstraction, and that below the point of abstraction (with which, in the present inquiry, we have nothing to do,) the law will insist upon the sewage being so dealt with that it shall no longer be an objection to sight or nose; but in dealing with the matter of water supply for drinking, no water should be taken where any pollution of any sort can enter. I am assuming also that as the loss of water in the Thames as it passes through the metropolis is an evil almost as great, if it be not quite so, as the tainting of the water with sewage, the companies will be bound to store water in winter for compensation in summer, and I am further assuming that the public insist upon having a constant supply at high pressure at the hands of the existing companies, so as to place their supply upon an equality with that proposed to be brought from Wales or Cumberland in that respect.

1695. Are we to understand that if the water, which is at present in a state of pollution, has that pollution removed, then for the sanitary uses of London it would be as good and as healthy as the water taken from any other source?—Exactly so, there can be no doubt about it.

1696. (*Sir J. Thwaites.*) Subject always to the question of the degree of hardness?—Yes, always assuming that.

1697. (*Mr. Prestwich.*) You collect your waters from very different geological areas, and I think you stated that above Lechlade you have made no experiments with regard to the quality of the waters. Have you made any experiments with regard to the quality of the water in any of the other districts?—No, I have assumed that there might be a trifling difference between the waters derived from the chalk, and the waters derived from the oolite; but the difference must be very slight, and, generally speaking, it is represented by a degree of hardness of from 13 to 14 degrees.

1698. The experiments upon waters from the chalk show that they generally vary in hardness from 12 to 19 degrees, whereas waters from the lower oolites vary from 16 to 25 degrees; therefore it is probable, is it not, that the waters from the oolites would be generally harder than those from the chalk?—Yes.

1699. Is there not this further fact always to be observed, that when those hard waters flow in long channels of a certain distance, they always lose a portion of their lime, and become reduced to one uniform level of 12 to 16 degrees?—Yes.

1700. Therefore you would anticipate that the waters from the whole of this district would reach London at a moderate degree of hardness?—Yes, 13 or 14 degrees, which might be reduced if the view which I have advanced is true, that by collecting water in large reservoirs a certain amount of precipitation would take place, which would reduce that hardness; and that it might be further artificially reduced by recourse to chemical science.

1701. (*Sir J. Thwaites.*) What is Clarke's process for reducing hardness?—The introduction of quicklime.

1702. (*Mr. Prestwich.*) Have you paid attention to the springs in the valley of the Kennet?—Not particularly; I have not gauged them.

1703. Do you propose to collect water from the valley of the Kennet?—Yes.

1704. And from the valley of the Wey?—If required. I believe that the whole of the tributaries of the Thames may be laid under contribution.

1705. In the valley of the Wey you get waters of a much softer quality, do you not?—Yes, they rise from the greensand, I believe.

1706. And those waters have been found to contain but a very small quantity of carbonate of lime?—Yes.

The witness withdrew.

Adjourned to Wednesday next, at 11 o'clock.

Wednesday, 13th March 1867.

PRESENT:

HIS GRACE THE DUKE OF RICHMOND, K.G., IN THE CHAIR.

Sir JOHN THWAITES.
Colonel HARNESS.
Alderman Sir BENJAMIN PHILLIPS.
THOMAS ELLIOT HARRISON, Esq.
JOSEPH PRESTWICH, Esq.

Professor A. C. RAMSAY, LL.D., F.R.S., examined.

Professor A. C. Ramsay, LL.D., F.R.S.

13 March 1867.

1707. I believe you are at the head of the Geological Survey department?—I am director of the Geological Survey of Great Britain under Sir Roderick Murchison, who is the director-general of the whole establishment, and I am Professor of Geology at the Royal School of Mines in Jermyn Street.

1708. Therefore you are well acquainted with the geology of Great Britain?—I am with the greater portion of it; with all that has been surveyed by the Geological Survey.

1709. And are you conversant with the district in Wales from whence Mr. Bateman proposes to bring water to the metropolis?—Yes, I know it exceedingly well; I surveyed the greater part of it myself geologically, and I have brought the geological maps here, which the Commission can see if they require to do so. The sources of the Severn are on the flanks of Plynlimmon, and I know the country well, and the nature of its geology.

1710. From your knowledge of the character of the country would you say that the water to be obtained from that district would be of a good character?—Yes; I should say that it would be soft. The rocks consist of slaty rocks, and grits and hardened sandstones, but chiefly of slaty rocks; and over the greater part of that area they are unfossiliferous, and contain little or no carbonate of lime.

1711. The waters are what are termed soft waters?—Yes.

1712. What is the character of the country; is it covered with heather?—I think there is a good deal of heather, but also a great deal of upland grass land. On Plynlimmon itself, for example, there is a great deal of grassy land where cattle are pastured.

1713. Is there much peat in that district?—My recollection is not sufficiently definite to say whether the ground is covered with much peat. There are in reality only two large peat mosses that I know of in Wales, and they are not mountain mosses, but in the plains. One is between Machynlleth and the sea on the banks of the river Dyfi, and the other is on the Teify in Cardiganshire, near Tregaron. The country, as a general rule, is not what I would call peaty.

1714. Those two large mosses that you speak of would not come within the district whence Mr. Bateman proposes to take water?—No; they are quite unconnected with it. The water that runs through them drains in opposite directions to the sources of the Severn altogether.

1715. If there is any peat in that district it is so small a quantity that it would not, you think, have any bad effect upon the water?—I have no doubt that the water would contain a little vegetable matter from the peat, because no hilly country of this kind is destitute of peat altogether, and a small quantity of peat here and there will serve to give a tinge to the water.

1716. Heather would grow upon the peat, would it not?—Heather grows upon peat, but not invariably or only there. Heather will also grow in a common soil. There are some peaty tracts, although I cannot remember precisely where they are, but it is not a peaty country in the sense in which Ireland is a peaty country, or that the Western Highlands is a peaty country, or that certain parts of Galloway are peaty.

1717. (*Mr. Prestwich.*) Have you noticed whether the streams are much discoloured by peat at any particular seasons of the year?—I have not noticed that, but my impression is that they are clear as a general rule, and that the water is exceedingly pleasant to drink. I drank a great deal of it in marching all over the ground in summer, and that is the impression which has been left upon my mind; but it is a good many years since I was there.

1718. (*Chairman.*) When you were surveying that country did you take any notice of the rainfall?—No, excepting that there is a great deal of rainfall; but I did not test it in any way. I made no observations upon that point.

1719. (*Mr. Prestwich.*) The analysis of the water shows the presence of a certain proportion and rather a large proportion of organic matter, which arises, does it not, in great part from peat and heather?—Yes.

1720. That analysis was made in the month of May, but the question is, whether in the fall of the year, in the late autumn, the quantity of vegetable matter would not be larger in those streams? Have you noticed at that time of the year that the rivers were discoloured from that cause?—No, I have not noticed that.

1721. Can you say whether this country is much wooded?—Very little; it is chiefly a high, unwooded country.

1722. (*Chairman.*) Is this district somewhat like Dumfriesshire?—It is very like Dumfriesshire, only that a great deal of it is rather higher; the ground on Plynlimmon rises up to 2463 feet, and a great deal of the country is 1,500, 1,600, and 1,700 feet high.

1723. (*Mr. Prestwich.*) Is there any great thickness of soil in the valleys?—There is a quantity of thick alluvial soil in the lower valleys. From Llanidloes down towards the Severn and the Tarannon rivers there is a good deal of alluvium.

1724. Do you see on the map the valleys where it is proposed to construct the reservoirs, which are marked in red?—Yes, there are three. There is one at Llanidloes, and there is a great deal of alluvium in that valley. That is on the river Tarannon, which joins the Ceryst. The whole of that valley where the reservoir lies, or nearly the whole, contains, I believe, a quantity of gravelly alluvium.

1725. Not silt?—I cannot answer positively, but I think there are sure to be silty alluvial beds on and mingled with the gravels.

1726. How is it with respect to the other three reservoirs?—There is alluvium in those valleys also, that is to say, in the valley of the Garthbibio, and Cann-office on the river Banw.

1727. (*Mr. Harrison.*) Would that be at the level shown upon Mr. Bateman's plan, or lower down the stream?—Where the reservoirs are marked upon this plan.

1728. (*Mr. Prestwich.*) Is the alluvium of a character, as you sometimes see in mountain districts, to form rich meadows and fertile soil?—Yes, grassy meadows; but as far as I recollect, though I am not quite sure about it, the substratum is chiefly gravelly.

1729. Do you think that the alluvium is of such a character that, supposing the valleys to be dammed up, and reservoirs formed upon their sites, it would act injuriously upon the water so collected?—No, I should think not. That is not the case in any of the reservoirs that I know of in other parts of the country for the supply of Liverpool and Manchester, and so on, in the Millstone-grit country, where I think there is sometimes a small stratum of peat, and it does not seem to injuriously affect the water. There is

another reservoir which is near Llanwddyn, and there is a covering of alluvium over the valley where the reservoir is drawn on the map. The name of the river is the Fyrnwy.

1730. (*Chairman.*) Are there any mines in that district?—There are no mines of importance in that district, or there were none such when I surveyed it.

1731. (*Sir J. Thwaites.*) When you say that district, do you mean the whole district from which Mr. Bateman proposes to take water?—Yes, when I was there there were no mines in that district of great importance.

1732. How long is that ago?—It is from 15 to 20 years ago since I surveyed this country. The chief mines of Cardiganshire lie on the opposite watersheds south and west of Plynlimmon. There are some in this district, but they were not of any serious importance. They may be of importance now, but they were not when I was there.

1733. (*Chairman.*) What mines were they?—They were, I think, all of them lead mines.

1734. Do you know at all how near the proposed reservoirs those mines which you are now speaking of are situated?—Whether they are in operation or not I do not know. There are some mines on the mountains to the west of Llanidloes, and the rivers of that country drain down into the Severn and into the Ceryst and the Tarannon. The rivers run through the country in which the mines are situated, and they drain into those rivers where the reservoir is proposed to be built. Further north in the other valley, the valley of the river Banw, there are no mines, or there were none when I was there, and I do not believe there are any now. It is not the kind of rock which experience shows contains ores of metals in that country. As to the third, at Llanwddyn, there used to be some small mines in that neighbourhood, but none of importance, and the rivers that drain into the valley of the Banw near Llanwddyn do not run through a mineral district.

1735. (*Mr. Prestwich.*) Have you the mineral veins marked upon this map so far as they were known?—Yes, so far as they were known at the time of the survey.

1736. Are there any ferruginous beds, or any likely to give rise to mineral springs and affect the water?—No, not to my knowledge. The rocks are not ferruginous any more than that any slaty or shaley rock always contains a little colouring matter, and a small proportion of iron.

1737. Do you know of the existence of any mineral springs within that district?—I know of no mineral springs within the district.

1738. (*Mr. Harrison.*) Will you refer to that plan which is before you, and follow up the river here called Afon Dyfi to the summit, taking the district between the watershed to the eastward, and the watershed to the west of the mountain of Dinas Mowddwy, and then draining into Afon Dyfi, what is the general character of the rocks?—The rocks that form the mountain range on the west, namely, the Aran Benllyn and Aran Mowddwy range, consist of feldspathic porphyries chiefly, and beds of Silurian volcanic ashes; and east of them, and lying on them, are a series of dark blue or black slates; then a little further east there is a thin strip of impure limestone, say 20 feet thick, known as the Bala limestone, but it is so small in extent that it does not seriously affect the waters of the country in any way; above that limestone there are more slaty beds, with a few thin beds of grit. The general character, therefore, of the country to the west of the river, is slaty, with thin beds of grit, and masses of felds pathic porphyries, on the extreme west, which always yield very pure water—the porphyries invariably do. Near the east of the river there are other slaty beds of the upper Silurian series. Those on the west of it belong to the lower Silurian series; and the water from the rocks of the upper Silurian series here will not, in any essential particular, as far as the rocks are concerned, differ from that which flows over the beds of the lower Silurian series.

1739. Is there any portion of the district which would be within that watershed containing beds of minerals at all likely to be worked in any way in those slates?—No; further north they have found some phosphatic minerals associated with this limestone, but I have never heard that they have been found in the valley of the Dyfi; and further north the quantity is so small, and the area is so limited, that it would not, in my opinion, in any way affect the quality of a large supply of water.

1740. Taking generally the watershed of that river, it would appear to afford over a large extent a stratification likely to yield the purest soft water, and water not liable to pollution by any working of mines?—It would not be polluted in the present state of mining in the country. That river drains in an opposite direction to that of the sources of the Severn.

1741. (*Mr. Prestwich.*) I presume that the country further to the south is a district in which it would be likely that trials would be made from time to time for minerals?—I know no reason why they should not, excepting that generally in the neighbourhood of these streams they have not been very profitable, as far as I know.

1742. Therefore, although they may show well at first, they would not be likely to lead to a large result?—Probably not. Mr. Warrington Smyth could answer such a question as that better than I can.

1743. (*Mr. Harrison.*) If you go further north to the watershed falling toward Bala Lake, would not the stratification be as nearly as possible similar to the watershed falling to the south-west?—As you go up to Bala Lake the rocks are of the same geological age as those which I have described; but there is this difference, that they become much more fossiliferous and full of Silurian shells, and therefore the waters which come out of those rocks would be more calcareous; still, these waters would not be so hard as to be what you would call hard water.

1744. From the analysis of the waters taken from Bala Lake, they appear to contain only about two degrees of hardness?—Yes, that is so; and the reason of that is, that the larger portion of the waters which run into Bala Lake come from the west and south-west of the lake, from the range of the Arenigs and Craig Aderyn. The rocks there consist of feldspathic porphyries, and the black slates that lie upon them directly are unfossiliferous or sparingly fossiliferous. East of Bala Lake the rocks become much more fossiliferous, and the water there I should expect to be harder than the water which flows in on the west of the lake. On the west of the lake, as far as I recollect, there is a considerable quantity of peaty ground in the lower part of the territory.

1745. (*Mr. Prestwich.*) Should you consider the Bala Lake district to be more peaty than the district which it is proposed to drain, and where the reservoirs are to be situated, or do you consider the surface vegetation of the Bala Lake district to be similar to that of the district proposed by Mr. Bateman?—Up among the mountains of the Arenigs the vegetation would be much the same, but round about the lake there is a very considerable amount of cultivation, and that would make a difference, or might make a difference.

1746. Is there more cultivation there than there is in the districts in which the reservoirs are proposed to be situated?—I think not much more than where the reservoirs are situated. There may be more than in the case of the upper reservoirs perhaps, and I think there is more cultivation in the parts of the country through which the water flows that runs into the lake than there is in those parts of the country through which the water flows to get into those reservoirs, supposing they were constructed. The lake country is, to a great extent, a lower country.

1747. (*Mr. Harrison.*) There is another large

Professor A. C. Ramsay, LL.D., F.R.S.

13 March 1867.

watershed, is there not, draining into the Twrch river?—Yes.

1748. What do you consider the general geological features of that district to be?—The greater portion of it consists of lower Silurian rocks, chiefly of a slaty character, interbedded with long lines of feldspathic porphyry, which is an igneous rock, and feldspathic Silurian ashes, of lower Silurian age; and on the flanks of the country there are the upper Silurian rocks which I spoke of before. The quality of the waters of that country so far as the rocks are concerned would, in the main, be similar to the quality of the water about Plynlimmon, or in the country south of Bala Lake.

1749. (*Mr. Prestwich.*) It is proposed to place these reservoirs at a height of about 500 feet above the sea level. Can you say whether the rocks there are in any way fissured or shattered in such a manner as to allow of the escape of water to the lower level through the sides of the hills, or the bottom of the reservoirs?—I should certainly not expect it—it is the last thing that I should expect.

1750. Are there any permeable beds at or above the 500-feet level by which some portion of the water might escape and be delivered to a lower level in the form of springs?—None that I know of.

1751. Is there any mass of permeable strata above the 500-feet level such as would absorb a portion of the rainfall and store it for subsequent and gradual delivery in the form of springs above the level of 500 feet?—There are porous rocks—the grits especially are more or less porous, and will absorb waters; and under favourable circumstances, which I am not prepared to say that I can point out at the present moment, there might rise to the surface waters in the form of springs, but the mass of the country consists of a rock which is not easily permeable by water. It is true that slaty rock is not easily permeable by water, though it does go through the joints and fissures such as they are; yet, as far as my experience goes, in the main, slaty rocks are singularly dry when you get into them.

1752. Is the country tolerably free from springs?—I am not prepared to say so or to deny it.

1753. Do you know of any porous strata there such as the oolites for example?—There is nothing of the kind.

1754. Then you would consider that the rainfall, except such as would be lost by evaporation and taken up by vegetation, would be all carried off by the streams and rivers?—The larger part of it.

1755. Would you consider that the delivery of the water follows soon upon the rainfall?—Yes, I should consider so from the nature of the country, but I have not made actual observations on that point.

1756. Should you consider, therefore, that the water delivery from such a district would vary very much from season to season?—Yes.

1757. Would it not be entirely dependent upon the actual rainfall of the season in each year?—Yes, it would be dependent upon the amount of the rainfall of the season; my experience shows that it is generally large, it is a very wet country.

1758. And very variable?—Of course it is variable, but there are many fine days and sometimes fine weeks and even months.

1759. In long continued droughts should you consider that the water supply would be dependent upon that which had been previously artificially collected in lakes or reservoirs?—I never knew a river run dry in that country.

1760. You have stated, I think, that the quantity of absorbing strata is small, and that therefore the springs are but small in their area?—Yes, as far as I recollect. It is not a country for springs like some countries that we know.

1761. I think you stated that the greater part of the surface was a hard rock surface?—It is a slaty rock surface, it is not the kind of surface into which a great quantity of water would percolate as a general rule; and the larger part drains off the country into the rivers, but the quantity of rain which falls throughout the year, although I do not know what it is, is so great that in the large rivers there is generally plenty of water.

1762. Are you speaking of where you get into the lower part of the country or above the level of 500 feet?—I should think that above the level of 500 feet by a good deal there is plenty of water.

1763. Should you consider it safe in a district like that, where you say there is but a small amount of rock which could absorb water and deliver it afterwards, to depend upon anything beyond the fall of rain from year to year?—If enough rain does not fall to keep the rivers running, and if you depend upon springs, I should say that it is a very bad thing to be dependent upon under those circumstances. But as I said before I have never seen the rivers with any lack of water in them. I stayed years in Wales backwards and forwards and water is the characteristic of it, but I cannot answer the question which you have put, namely, whether if there were no rain to fall for six months or some such period as that there would be a sufficient quantity of springs to keep the reservoirs full. I have no information upon that subject.

1764. My question was not intended to convey that, but you say, do you not, that the surface is composed essentially of hard slaty rocks?—Essentially so.

1765. And that there is nothing to absorb water and store water and give it out by slow degrees?—If so it is exceptional. All slaty rocks are apt to be decomposed for a good many feet below the surface, and they would be permeable by water to that depth.

1766. But they are not capable of storing water like the oolitic or cretaceous strata?—No, not to store it like those strata.

1767. Therefore, in a district like that, you could not in a year of small rainfall look to any previous subterranean storage of water to increase the minimum rainfall of that year?—I should think not in any serious degree.

1768. In estimating the quantity to be delivered you must base your quantity, must you not, rather upon the minimum rainfall?—You must place your dependence upon what flows off the surface in any particular year or part of the year.

1769. (*Mr. Harrison.*) You did not make any observations, did you, on the rainfall when you were in that part of the country?—No, no precise observations.

1770. (*Mr. Prestwich.*) It is a very rainy district you say?—Yes, it is a rainy district, all Wales is.

1771. (*Mr. Harrison.*) Taking the geological features of this particular district which you have been describing, do you think that it is as favourable as any other geological strata in England for the supply of soft water, or could you point to any particular district that would yield a purer water?—No, I do not know any district in England that would yield a purer water. The water of the Silurian rocks in any part of England or Wales is very much the same. The general structure of this country strongly resembles part of Westmoreland and Cumberland, the rocks are of the same age and their lithological character is tolerably similar.

1772. (*Chairman.*) Are you acquainted with that part of the country which we call the lake district?—Not at all so intimately as I am with Wales. We have just begun to survey it, and therefore I do not know so much about it.

1773. If you look at the map before you containing the district of Ullswater you will observe the part coloured blue and the part coloured pink just below it, in which are situated Ullswater, Thirlmere, and Haweswater; do you imagine from the character of the country that the water would be good for the purposes of the metropolis?—I have never been in that country, but it is quite notorious what the nature of the rocks is—I know what to expect if I were to go there, and I should find what I expect—and the water

ought to be in a general way as far as the rocks are concerned of the same quality as that in Wales.

1774. Geologically speaking, would you imagine that the water which could be obtained in that district would be as good as the water that you would find in Wales?—I would expect the water to be the same as nearly as may be.

1775. You think that there is no reason geologically why it should not be?—The general character of the country is the same, it is formed of the lower Silurian rocks. Part of the area coloured blue on the east, as far as I can make out by a comparison of the maps, consists of limestone, but I have not surveyed the country and do not speak from personal knowledge. Further south and south-east I know the country, but not where it is coloured blue on the map.

1776. Are you aware whether there are any mineral formations in that district?—I am not aware. In the part that I know there are some iron mines, but that is further south, and quite out of the district.

1777. (*Mr. Prestwich.*) It frequently happens, does it not, that under the alluvial soil of a valley there is a considerable accumulation of gravel following the course of the valley?—Yes.

1778. With regard to the sites of Mr. Bateman's reservoirs in Wales, where the dams are proposed to be placed, should you consider that the gravel underneath the alluvial soil in those spots would be of such a thickness as to interfere with the construction of the proposed works, or does the rock at that point come near to the surface?—I do not recollect.

1779. You have walked over the greater part of the Welsh district, are there many villages or hamlets there?—No. In the upper grounds where the water gathers there are very few. It is a high pastoral country for the most part, with a few scattered farmhouses; there are no villages of any importance until you get into the great main valleys where the larger rivers run.

1780. Down at the points where the dams are proposed to be constructed are these villages or collections?—There are no large villages or collections of houses except the town of Llanidloes itself, which is a good sized town, but as a general rule the villages are exceedingly small. Trefeglwys, for example, is a very small village.

1781. Is there much of the land under cultivation?—A great deal of the land is under cultivation on the flanks of the great main valleys.

The witness withdrew.

The Reverend James Charles Clutterbuck examined.

1782. (*Sir J. Thwaites.*) You are a clergyman, and you have given considerable attention, have you not, to the supply of water to large towns?—Yes, I have.

1783. And to London in particular?—Yes.

1784. You are fully acquainted with the watershed of the Thames?—Yes, I am.

1785. Can you inform the Committee as to the geological character of that watershed, and how it may affect the water which ultimately flows into the Thames?—The watershed of the Thames, commencing with the lower part, which is the upper geological series, begins with the London and plastic clays and the chalk formation, including the upper greensand and the gault. Beneath that is the lower greensand and the oolitic strata down to the Lias clays. The great source of water supply to the Thames is decidedly the chalk proper, the upper and the lower chalk, and especially we may say the upper chalk. There is a source of water to the Thames in the upper greensand. The gault is a retentive stratum, and being clay of course is not a water-bearing stratum; and beneath that there are traces or patches, as we may call them, of the lower greensand. Then there is the Kimmeridge clay, which is a retentive stratum, and therefore yields no water, and below the Kimmeridge clay you have the oolite. The Portland oolite is distributed here and there above the Kimmeridge clay. Below the Kimmeridge clay we find the coralline oolite, which is also a source of water supply to the Thames. Below that is the Oxford clay; and again below that, cropping out in the Cotswold hills, are the larger oolites, and the lias formation, consisting of the upper lias clay, which is a retentive stratum, and the marlstone, which yields a certain quantity of water, and the great body of the lower lias clay, which upholds the whole of the water in the oolitic strata. That is, I think, a general view of the geological structure of the valley of the Thames.

1786. Do I rightly understand the substance of your answer to be that the largest portion of the water due from the watershed of the Thames basin is from the chalk?—Decidedly; that is a point I wish to make.

1787. Have you turned your attention to the properties of that water as to degrees of hardness?—The degrees of hardness in chalk water are very well known; they are known to be from 17 to 20 degrees of hardness. I think that is the scale which is generally given. It is known to be a hard water, such as is supplied to London from the Lea. I think that would be one of the best types of the chalk water; however, that comes out in analysis; it would be a type of the water from the chalk. I am not a chemist, and therefore I do not attempt to speak with certainty upon that point.

1788. (*Mr. Prestwich.*) By the Lea do you mean the New River water?—Yes; the water supplied by the New River Company.

1789. Such as was originally delivered in London by the New River Company?—Yes. I will confine myself to that, and say that that is a type of the chalk water; you will find it a hard water.

1790. (*Sir J. Thwaites.*) When we speak of a geological basin and its yielding power, that would be somewhat dependent, would it not, upon the fact as to whether that basin has been tapped by artesian wells or otherwise?—Decidedly it would.

1791. If there is a drain upon a basin by means of artesian wells the general yield of that area would be lessened?—Decidedly.

1792. What is the condition of the watershed connected with the Thames in that respect?—All the district in London and round about London has been tapped by artesian wells, and there is a depression under our feet of, it may be, 60 feet below Trinity high-water mark. I think that has been established. I read a paper at the Institute of Civil Engineers in 1850, of which I have a copy here, showing that has been the depression in consequence of the pumping of the different establishments in London.

1793. From what has it been depressed?—As far as I can gather from the facts which have come under my knowledge, and I have had access to a great many, the state of the case appears to be this, that originally, previously to any tapping by artesian wells, the level to which the water was regulated was Trinity high-water mark, as near as may be, or perhaps the mean level of the Thames where the sand outcrops in the Thames, which is about Deptford. As far as I have been able to gather from the way in which the establishments in London—the great breweries and distilleries and other places—have tapped the water in the chalk, the depression is in round numbers 60 feet below Trinity high-water mark. The Commissioners will find very much information upon that subject in a book of Mr. R. W. Mylne, in which he has published subterranean sections of the London basin, which are exceedingly valuable, and, I believe, may be thoroughly relied upon. As I have said, the depression is 60 feet below Trinity high-water mark, running up at

Rev. J. C. Clutterbuck.

13 March 1867.

an angle into the country, because no subterranean water is flat, it is always lying at an angle; for instance, it will stand above Trinity high-water mark at Cricklewood, and it is depressed 60 feet below Trinity high-water mark in the centre of London.

1794. Have you directed your attention to the power of absorption within this area?—In order to meet what you wish to know, will you allow me to say I do not think that the depression of the level of the water seriously affects the yield; it has not been traced, and I have never been able to trace it to the springs above; it seems to have been confined to the depression, so that those who use artesian wells have merely deprived themselves of water.

1795. I do not think you quite apprehend my point, which is this, that a basin full or a basin empty will seriously affect the amount of water due from a given area?—Yes.

1796. And the absorbing power of the earth would necessarily be greater if you tap the lower part of the basin by means of those artesian wells?—Exactly.

1797. I want to know whether your attention has been directed to the watershed of the Thames, and whether, having regard to its general flat character, the absorption would not be very considerable when you take into account the fact that it is tapped at the different points to which you have referred?—You mean that there would be a loss of water to the basin from that tapping.

1798. Take the case of an ordinary basin of similar geological formation, and of surface equality, not tapped, and a basin of a similar character tapped as the London basin is obviously tapped, would the power of absorbing a large amount of rainfall be greater in the London basin than in a basin that was not so tapped?—I think the power of absorbing an amount of rainfall would not be affected by tapping. I think that the overflow from other parts might be affected, but I think that the water would just in the same way have been absorbed; the difference would be that it would have been delivered out in a different way. It is taken unnaturally, or in an artificial manner, instead of flowing out in a natural way. I do not think that the absorption of the water would make much difference, but the delivery of the river above might be affected by it.

1799. Supposing there were no tapping at all, and the basin were filled up to the surface, saturating every part within a given measurement of the surface of the ground, it is clear that the rainfall could not have been absorbed, except to a very limited extent; but if you are tapping that basin at a lower point, and drawing off the water at the upper point, the absorption must be greater, must it not, as it appears to me, than if it were not tapped?—I think, from the peculiar nature of the chalk, though it might not seem reasonable at first sight, that is not the case. I think there would be the same quantity absorbed. The only difference would be that it would be delivered out in a different way. It would be delivered naturally in its outfall into the river Thames below London if it were left to nature, but if it were abstracted, as it is, it might quicken the delivery from above, and prevent so much water issuing from the streams, but I do not think that the absorption would be affected by it.

1800. Could those lower streams be available for the supply of water to the metropolis?—If you mean the springs under our feet in London, they would be available as far as they go, but they have been taxed already too heavily. The supply has been over-taxed, and the consequence has been that there has been an unnatural depression. The water has been taken quicker than it naturally comes, when it is naturally delivered, and it is drawn down at an unnatural angle.

1801. Do you think that the yielding capacity of the water stored in the London basin has been mastered by the several wells which have been sunk?—Decidedly so as regards the lower part of it.

1802. And that any hope of obtaining a supply of water for the metropolis from that source would be a failure?—Yes, an utter failure.

1803. (*Mr. Prestwich.*) Are you speaking now of the chalk beneath the tertiary strata—beneath the London clay?—I am speaking of chalk beneath the London clay. Here is a section (*producing the same*) upon which I can rely, showing the whole of the line of water, and showing the point at which the waters are depressed. There is no delivery of water above ground further than at this point (*pointing out the same on the section*).

1804. (*Sir J. Thwaites.*) What number of miles is that from the metropolis?—I suppose it must be about 13 or 14 miles from London, but there are places nearer to London, in the direction of Surrey, where the water comes above ground; but the water that supplies the greatest part of the artesian wells in London on this side of the Thames comes from the north, and there is no water delivered above ground, I suppose, within 12 or 14 or 15 miles.

1805. You are well acquainted, are you not, with the surface condition of the watershed of the Thames for some hundred miles up?—Yes, all the way.

1806. Is it highly cultivated?—It is highly cultivated, decidedly.

1807. And what, in your judgment, would be the effect upon the water in the rainfall passing through a soil so cultivated?—With reference to the chalk surface, I do not conceive that there would be any great amount of effect produced by cultivation on the water percolating that part of the country, because it would sink through so very much soil. First of all, according to what is held by Professor Way and others, the soil would entirely deprive it of any of its organic matters, or rather, if it took up a little on the surface, it would be deprived of it before it got far down; at least, I think so.

1808. The filtration would probably deprive it of all matters in mechanical suspension, but would it of all matters in solution?—I will answer that question in this way, judging by the analyses of this water I have seen, there has been scarcely a trace of any organic matter in it.

1809. But that would not apply, of course, to the water which finds its way into the river. It is proposed to intercept and utilize the flow from those rivers of the water which passes off immediately from the land without being filtered through chalk or anything else. What would be the condition of water under such circumstances?—First of all, that has reference to the retentive strata. I think that you have got a map, which is coloured after the same fashion, as in a paper of mine on the Thames which I read at the Institution of Civil Engineers. In that I have only taken the upper part, but this map gives you the whole.

1810. Looking at that general condition of the surface and at its geological formation, is there in your judgment any objection to that gathering area for water for the purposes of domestic use?—No, I think not, I cannot say that I see any. Of course the water would be turbid in many places from flowing off the clays. The first clay which you have to deal with would be the London clay. You are aware that there are a certain number of reservoirs for the supply of the canals; there is one at Elstree, and there used to be one at Ruislip. I think that is done away with, but the former I believe exists still, and there are a certain number of other reservoirs. There is one between Cricklewood and Edgeware.

1811. Those waters have been gathered I presume in the ordinary way?—Yes, they have been gathered in the ordinary way; they come turbid to the reservoirs, but if they were allowed to go through the process that the London waters are by filtration they would part with all or almost all their objectionable properties.

1812. (*Mr. Prestwich.*) You state that there is a great exhaustion of the water in the chalk beneath London, does not that arise from the difficulty of transmission and from the flow of water from the outcrop of the chalk to beneath London being exceeded by the

extent of pumping at the different London wells?—That is exactly the case; it does not come to the place whence it is raised sufficiently quickly to prevent that depression.

1813. Is not that depression extremely local?—Decidedly.

1814. How does it affect the chalk at its outcrop?—I never could trace it to the outcrop. The water rises and flows down the rivers there.

1815. Do you consider the springs in the chalk area to be unaffected by the pumping underneath London?—I think so, at any rate I cannot trace it; I have tried to trace it in vain. I have never been able to trace that the quantity raised in London has any visible effect upon the waters in the outcrop; the waters would naturally flow in a certain quantity here, and they are intercepted before they get to their natural outfall, and they do not come quick enough to maintain the natural level at which they would fall out.

1816. With regard to the absorption in the chalk area, the surface of the chalk above the line of water level would always absorb water irrespective of the delivery by springs or pumping by wells, that is to say, the absorbing action of the chalk surface would always proceed and be unaffected, would it not?—Entirely; the absorption and the delivery are two different things. The absorption would be just as much if there were no bottom to the chalk as if there were; if you could pump all the water out the absorption would not be at all affected by the way in which the water is pumped out from below.

1817. Then the springs in the chalk you consider to be still in their full force?—Decidedly, I think so.

1818. You have described the very variable series of strata which serve to form the drainage area of the Thames valley and its tributaries, taking the whole of the area, have you not?—Yes.

1819. You are aware, of course, that generally on a large scale the delivery by rivers is upon the general average in these latitudes equal to about one-third of the rainfall of the area which the river drains?—One-third, I think, is a liberal allowance.

1820. But that one-third is made up of very different sums in the different strata?—Decidedly.

1821. That is to say, that there would be a larger immediate delivery of rain falling on slate rocks, or on clays, whereas the rain falling on oolitic rocks and chalk would be absorbed for future delivery?—Decidedly.

1822. Can you give us some idea of the extent of the chalk area within the Thames district?—I have not measured it but it is very extensive. I scarcely understand whether the question refers to the upper Thames above the pumping district or whether it includes the New River Company.

1823. My question had reference to the upper Thames?—When I am speaking of the upper Thames I mean everything above the tideway. It extends from beyond St. Alban's to Marlborough in a line. I cannot tell you the area because there are spots which are covered by a retentive stratum of clay, or rather beds of plastic clay here and there dotted about as they are marked upon this map, therefore those do not absorb the water in the way that the chalk does where it is not covered with these retentive strata, so that it would be difficult to reduce it to a measurement, though it might be measured. It is a very large area.

1824. Of several hundred square miles?—700 or 800 I should think. It might be easily estimated, but it is very large. I would take out one-sixth or thereabouts for the retentive strata.

1825. (*Sir J. Thwaites.*) When you speak of the yielding power of any given area having regard to the amount of rainfall upon the area itself and gauging the river or rivers that carry off the net result after allowing for absorption and evaporation, is there not this difficulty, that it is probable that some spring actually within that area, having regard to the geological formation, may yield water due from another gathering area; or to put it in other words, supposing we had an area of 600 square miles, and we were anxious to ascertain first the amount of rainfall upon that area, supposing it were to be 30 inches, and to ascertain the net result after allowing for absorption and evaporation and so on, in order to get at that result you would have to gauge the rivers as they flow out of that area?—Yes.

1826. Would that be a reliable test as to the net result of the rainfall due from that area, might it not be interfered with by springs flowing from the geological cropping out as it were or the overflowing of a basin which really collected the water in another area?—With reference to chalk, I should say decidedly not. Without going into the reason why, I think I may say decidedly that would not be the case. I think all the water from the chalk is due to the chalk; every spring that you find flowing from the chalk is water which is received on the surface of the chalk and flows from it. I never met with anything that made me think otherwise, except in this way, that where there may be a capping of gravel which has a seam of clay underlying it, sometimes a little water will flow out of it, but it will flow down into the chalk at the lip, or rather at the margin of this retentive stratum. There are such cases, as at Abbotts Langley in Hertfordshire, where there is a stratum of plastic clay overlying the chalk that upholds sufficient water to supply the inhabitants. Where it flows out in springs over the margin of the clay it at once sinks into the ground. I had a striking instance of that, I was measuring some wells with very great nicety, in order to see what effect certain pumping had upon the chalk water. I found that one of the wells was thrown as it were out of gear; it showed a height of water which I could not account for. I found that there was a pond in the bed of clay, the head of which had been cut, and the water let out. Directly it touched the chalk the water sank into the chalk, hence the water in the well had risen. So all along the outcrop of the tertiary strata there is water which runs into the chalk from the surface of the London clay, which sinks into the chalk when it gets to the junction of the plastic clay sand and the chalk through swallow-holes; that is the only exception I know; that is easily seen and accounted for, but I do not know any spring delivering from the chalk which derives its water at all directly from any other source but the water which sinks into the surface of the chalk itself.

1827. (*Mr. Prestwich.*) Do you consider that a large proportion of the rainfall passes directly into the chalk?—Yes, about one-third of the whole.

1828. If a large proportion of those claybeds cap the chalk hills, does not a certain proportion of the water falling on them pass into the chalk when it flows off those claybeds?—Yes, decidedly.

1829. How is this water which passes into the chalk delivered?—It is delivered again by springs wherever there is a valley of a river; wherever there is a place where it can get out it rises till it finds its outlet.

1830. Are the springs in the chalk area with which you are acquainted numerous?—Yes, very numerous; they are in valleys, and wherever they can get out they come out; they are very numerous and very strong.

1831. Besides that general issue of water on the line of the water-level in the chalk valleys, are there not springs of greater strength, such as the springs at Amwell, and such as the springs near Hungerford?—They are very strong indeed, and they are all to be accounted for by the contour of the country.

1832. Are you acquainted with any district where those springs are numerous, and such as would be capable of affording a large supply of water?—Yes.

1833. Can you mention any particular springs, or any particular place where such springs are common?—They generally come down the valleys in the way of streams; about Watford in Hertfordshire there is a spring yielding an immense quantity of water at a place called Otter's Pool; that is a very large spring from the chalk, and all down the valley of the Colne there are springs. I may express it in this way, that the rivers in the chalk run on the back of the springs.

1834. (*Sir J. Thwaites.*) It was suggested, was it not, some years ago that a supply of water should be

Rev. J. C. Clutterbuck.

13 March 1867.

obtained from the Watford basin?—Yes, it was proposed to sink large wells, and I had my attention first drawn to the question of water supply in the chalk in consequence of watching the effect produced by the pumping; I could trace the pumping every day; I knew when they were pumping and when they were not in that district; I have recorded the whole of that in a letter to Sir John Sebright.

1835. You think there could be no hope of obtaining a sufficient supply from the Watford chalk?—You would obtain a certain quantity, but it would be at the expense of the rivers; the rivers would cease to flow. When my advice has been asked I have invariably said, Take the water as it flows above ground, and do not tamper with it below; that is what I have invariably said, and I believe it is sound advice.

1836. (*Mr. Prestwich.*) I was asking you with regard to springs, not with regard to wells, whether you know of any springs of great volume and great strength in the area of which we have been speaking?—There is a very great volume and a very great strength at Amwell spring; I do not know the state of it at present because I have not seen it lately, but along all valleys in which rivers run, the Kennet, for instance, the chalk streams are fed from their sources down to the place where they deliver themselves into the river, because they run just on the springs, and are fed as they go. You may not see very large springs, but you will see an immense gathering of water in the course of the river by the discharge of the water from the springs.

1837. Do you know the spring near Hungerford or rather Froxfield?—I do not know that.

1838. Do you know the spring at Shalbourn?—I know the river but I do not know the springs; I attach less importance to individual springs than I do to the yield in the aggregate.

1839. (*Sir J. Thwaites.*) Are you of opinion, having regard to the condition of this watershed, that by proper catch-basins and engineering arrangements a sufficient quantity of water might be stored for the supply of the metropolis?—I have no doubt about it, taking the water as it flows down the river, not tampering with it by pumping or anything of that sort, and by an arrangement of storage in the upper districts such as those reservoirs which supply the summit level of the Oxford canal and other places, I believe there might be an immense storage of water in the upper districts.

1840. Which are the districts that would be most favourable for the formation of reservoirs?—The most favourable would be a district where the lower lias clay forms the bottom of the valleys.

1841. What part is that?—The district of which Banbury and Stow-in-the-Wold are the centres, having regard of course merely to the watershed of the Thames.

1842. As to the levels, you have, perhaps, not paid much attention to that branch of the question?—No, I have not had an opportunity; there is quite sufficient height to ensure their delivery.

1843. Would the point of their delivery be at high water?—Yes, they would be delivered into the rivers, and the rivers would be the means of delivering them into London. I have never contemplated the delivery of water into London from those sources at a higher level than the river itself.

1844. Then what would involve pumping of course?—Of course it would. You might, perhaps, by some very expensive contrivance, bring those rivers from their sources to London at a high level, but that would be a most extravagant way of doing it.

1845. Could you have sufficient fall?—Yes, you would have sufficient fall, but I think it would be a wild scheme.

1846. (*Mr. Prestwich.*) Would it not be possible to bring the springs from the chalk area to London from Buckinghamshire district at a high level in the same way that the new river brings water from the springs at Amwell?—Yes. There is no doubt whatever that the water from the chalk in many cases might be delivered into London at a higher level than it is at present.

1847. In the same way could you not bring water from the oolite hills of Oxfordshire and Gloucestershire, they being at a height of 200 to 300 feet above the Thames, and could not the springs from that district be brought to London by gravitation at a high level only at a greater cost?—Of course it might be done. I will not say anything about the cost.

1848. (*Sir J. Thwaites.*) Has your attention been directed to the probability of obtaining a supply of water for the metropolis other than from the Thames basin?—Yes; I have read the pamphlets of Mr. Bateman and Mr. Hemans with reference to that subject, which propose, the one to bring the water from the Welsh hills, from the sources of the Severn, and the other from the Cumberland lakes, projects which are well known, I believe.

1849. Does there appear in your judgment any serious objection, apart from the question of cost, to the schemes which have been generally considered?—One of the objections which struck me with regard to the scheme proposed by Mr. Bateman was, that he had not sufficiently shown that the watershed there would yield the amount of water that he calculates upon. In the first place he has not sufficient information with reference to the average quantity of rainfall, not that I attach much importance to the averages of rainfall. I think that all rainfall with reference to the areas which are to supply water to London must be considered with regard to the minimum, whatever that is—what shall be the minimum of rainfall, and what shall be the possible duration of drought which may deprive you of water at a certain time. The objection as it appears to me to Mr. Bateman's plan is that you have no certainty that you shall not at some period be deprived of water.

1850. Then your objection would be to taking an average at all?—Decidedly.

1851. And for the sake of safety you would take the minimum fall and all plus that would be gain?—The only thing to set against that would be the natural or artificial storage of water in those lakes, but when you speak of that as a supply of water which you are to depend upon you must take the minimum, as it appears to me.

1852. You are aware are you not that Mr. Bateman has allowed himself a considerable margin even below the average?—I am fully aware of that.

1853. Do you think that that reduction would be a safe one, on which the Commission might calculate that the yield would be equal to that which has been stated?—I should have some hesitation in answering that question, but the impression upon my mind is that there are deductions which perhaps people are not quite aware of, and that I would trust to nothing but a series of gaugings of those rivers which deliver the water, so as to get the net result.

1854. I suppose the gaugings in Wales have not been extended over a sufficient period to enable you to come to a conclusion?—I have perhaps read the pamphlet rather hastily, but I do not remember that there is anything like a gauging of the rivers mentioned, and without gauging the rivers I think you have no security, because you cannot tell in that country how much is evaporated, you cannot tell how much is absorbed, and there may be runnings of water which are delivered out at other levels that you know nothing of. It appears to me that in that peculiar structure of country there may be a leakage of water which you have not calculated upon. If it could be shown in a series of years that a certain river at a certain point yielded a certain quantity of water, then I think that you might deal with it, but I should be very much afraid of dealing with mere calculations of rainfall and area. No doubt the most reliable information would be to have the rivers gauged at their outfall, to ascertain the net result; that is much safer than depending upon any average rainfall. As compared with the chalk, you have no means of gauging the subterranean water, but I now gauge the subterranean water of the chalk by a line of wells in Hertfordshire, and am able to determine with very considerable accuracy how much water there is in the chalk; I have ascertained that

this year there is above the average quantity of water in the chalk to be delivered out, because I have measured that line of wells, and I find this will be the result. In a paper I wrote for the Agricultural Society there is a diagram of it, and I confidently rely upon that diagram, so much so that I have been able to tell within a day when some of those bournes would burst that there are in the upper district. I have been able to write to friends of mine in three or four different districts, and say, knowing that there was a certain quantity of rainfall, and knowing that those levels of wells had risen in a certain ratio, "You will find that your bourne shall burst within a week;" and it has been so. I have never been out in that calculation, and I feel as confident of it as possible; but you have no such means of gauging the waters which issue to a certain extent in the springs in those mountainous districts, and there may be a loss of water that you are not aware of, but if you have the gaugings of the rivers you can say decidedly that those rivers yield a certain quantity of water every year, that the average is so much, and you have never known them fall below a certain volume. I observe that Professor Ramsay thought there was always water enough in the rivers, but I know that there is nothing so deceptive as that. I have been told hundreds of times This is a spring that never fails, and it never varies. I say directly I know that that is not true. Here is the line of wells that I measured (*producing a section*). The lowest line is the level of the river, and the other is the line of water level. You cannot draw lines truer than those shall be. When I have measured one or two of the wells I can tell directly how much the ratio of variation is. As registered here it is 10 feet in one place and it is 1 foot in another. You can gauge the water in the chalk just as you can the water in a tub. I speak very positively upon that, and I am quite sure that I should be enabled to gauge the water in the chalk at any time, and I should be able to tell you that you should have a certain quantity at a given time. It is well known that Messrs. Dickinson, the great paper makers, make their contracts by a rain gauge. They have a gauge which registers that quantity of water which sinks through a certain amount of earth called "Dalton's gauge." I have tested it by the wells, and gauged the wells, and I can speak positively with reference to the probable yield of water from the chalk.

1855. You would not advise this Commission to be satisfied with merely obtaining information as to the amount of rainfall upon the theory that so much is absorbed and so much evaporated, but you think that we ought to have some information as to the quantity of water that flows off as the net result of all those operations?—Decidedly. I have not the least doubt about it as comparing the other districts with the chalk, I think that the chalk is quite different; you might go into the chalk at any time, having a previous knowledge of the condition of the water in the chalk, and you might gauge the water in the chalk; but I say it cannot be done in those other districts.

1856. (*Mr. Harrison.*) Your objection to Mr. Bateman's scheme appears to be based upon the ground that you do not think there would be sufficient water according to his calculation?—I am not satisfied that there would be.

1857. You have been present here while Professor Ramsay was being examined. Assuming that there are other districts, going northwards even as far as Bala Lake, and that it were practicable to bring double the area that Mr. Bateman has calculated upon into one and the same conduit for supplying London, perhaps you would not feel much difficulty in saying that a very large margin might be safely given to Mr. Bateman's calculation?—Yes, if you extend his area. I believe there might be an area so extended that you might have no doubt whatever upon the subject; but taking his area of 66,000 acres in each of those two plots, I should not be satisfied, if I were asked my opinion, that it had been proved to me that there was a sufficient yield; and if I were asked the reason why, I should say because the net result of the water from the district has never been put before me.

1858. Mr. Bateman has based his calculations upon the assumption that you could depend, even in a dry season, upon having 36 inches of rainfall available. Assuming that that should prove to be a mistake, but that he could add 50 per cent. to the gathering area, and bring it all into the same conduit, taking it in that case that you can only calculate upon 20 inches of water, do you think that we might safely calculate upon 20 inches of water in that hilly district from any knowledge which you have of it?—I should say that the probabilities were in its favour.

1859. You would not go further than that?—No, because I do not know enough of the circumstances of the district.

1860. But still, assuming that data really do not exist from any sufficient number of observations of rain gauges to find out the average at the present moment, and that Mr. Bateman has made all his calculations upon the assumption that you could have 36 inches available, if he could show that, in order to meet any possible deficiency, he could even double the area of his gathering ground, and bring it into the same conduit, that would at once get over the difficulty?—The probabilities would be in its favour. I could not venture to say more than that.

1861. (*Sir J. Thwaites.*) Having regard to Mr. Bateman's statement that the average rainfall in Wales is 48 inches, and that he struck off 12 inches from that as a margin for contingencies that could not be accounted for, do you think that 36 inches would be a fair and safe amount of water for us to anticipate from a given area?—I think it would be too much, but I cannot speak positively. My impression is that you would not get that quantity.

1862. (*Mr. Prestwich.*) In any case, should you not, as a geologist, look to the circumstance that in a district composed of absorbent strata the rainfall would be stored for the present, and delivered during a course of time, dependent upon the mass of the absorbent strata, whereas in a hard rock district, such as Wales, or in a slate district, should you not consider that the rainfall, not being absorbed, would be delivered immediately, and, therefore, would it not be necessary to take the minimum rainfall, and not the mean rainfall of a certain number of years for calculating upon the water supply of towns?—I would always take the minimum rainfall everywhere, but I would be more careful to take it in that district, because from the nature of the district, throwing the water, as we are presuming it does, from the surface, I am at a loss to know how you would get a permanent amount of water without an immense storage over and above what nature has given.

1863. (*Sir J. Thwaites.*) Or to provide for droughts?—Yes, your storage must be immense.

1864. (*Mr. Harrison.*) It is proposed by Mr. Bateman to provide very extensive storage, but it is a question whether he has provided enough, according to your view of it?—I do not speak so much of the storage as I do of the properties of the rain.

1865. (*Sir J. Thwaites.*) You are sufficiently acquainted, are you not, with the Welsh district, and also with the lake district, to form an opinion?—I know little about them. I know the general aspect of them.

1866. So as to form an opinion that they would be unobjectionable as a gathering ground?—I presume that they would yield you a water which would be very free from impurity. I have reason to believe that.

1867. (*Mr. Harrison.*) I gather from your remarks that you are decidedly against any question of pumping from the chalk?—Most decidedly so.

1868. If the Thames basin is to be used for getting pure water, you would go as near as possible to th fountain head?—Decidedly.

1869. Taking it from the springs arising directly from the chalk measures?—Yes; I cannot speak too strongly upon that point, it is a battle which I have been fighting for the last 25 years.

1870. (*Mr. Prestwich.*) Have you gauged any of

Rev. J. C. Clutterbuck.

13 March 1867.

the springs in the chalk area?—No, it is a thing I have never done, because I have always looked to the aggregate supply of water from a given stream. We know the Colne, for instance, and the Kennet, those two perhaps might give about the same quantity of water. And then there is another point which I have insisted on, and one which I have every reason to believe is well worthy of your notice, and that is the quantity of water which is received into the bed of the Thames itself. The little rivers which are in the chalk and which come down the valleys in the chalk, receive the drainage of a large portion of the chalk, but if you look at the map you will find that from Moulsford and down towards Henley there is a very large district which has no natural drainage at all, but it has its drainage into the Thames itself. Mr. Harrison, the brother of the Commissioner, asked me a good deal about that question, and it was a good deal with a view to that that I went and made a section to show the course that the water must flow into the Thames from there. Here is a little section (*producing the same*) from Streatley, something less than a mile up into the country. That lower line shows the mill-tail, the water lies in the chalk about 18 feet above the river, at less than a mile from it (*the witness explained the section to the Commissioners*). This shows that the natural drainage must be to the river.

1871. (*Sir J. Thwaites.*) How do you account for the difference of level?—Because the water always flows on an incline, I have seldom known it less than 14 feet in the mile and never less than 10 feet.

1872. Is it the retentive quality of the holding stratum that gives that difference of level?—It is the friction, it is the resistance that the water meets with in its passage through the interstices of the chalk which makes it take that incline; that is the balance of the friction and hydrostatic pressure. For instance, if you pump from a shaft in the chalk you will find that the water around it is depressed in the form of an inverted cone; you will find that the first foot or two will come down very easily, but inasmuch as you increase the pressure of the water into the shaft, as you get lower down the water will be reduced very slowly, and at last if your pump is not very strong it will be reduced to a point at which it will stand, so that you may pump away, and it will not vary an inch for a long time. Then if you take the pumps off, the water will rise in the shaft in the inverted ratio of its reduction. The natural rise and fall of the chalk water is so beautifully regulated that you may rely upon the chalk gaugings when you cannot rely upon any gaugings in other strata.

1873. (*Mr. Harrison.*) The terms of the Commission point, I might almost say confine the Commission, to the idea of obtaining water from grounds by gravitation, so as to afford a constant high level supply to London; that being the case the views which you have given as to taking the water from the springs in the chalk would hardly be available to carry out that idea, but taking the higher level of the Thames could you give us any idea as to this; assuming that 400 feet above Trinity datum was the minimum point at which you would have to take those waters, would you get a sufficient watershed to supply the consumption of London at the rate of about 250,000,000 gallons a day?—No, certainly not.

1874. Could you give any idea of what that 400 feet would supply?—No, I could not warrant anything at 400 feet.

1875. (*Mr. Prestwich.*) Except the small tributaries?—No, besides that if you did that you would be, if I might be allowed to say so, robbing the Thames; you would reduce the Thames very much.

1876. (*Mr. Harrison.*) Possibly we might take a less height than that, say 300 feet, what would it be?—I do not think that would be worth having.

1877. Then the result practically would be this, that it would be impossible to comply with what the terms of the Commission seem to press upon us, namely, to supply water at a high level by gravitation from the Thames basin at all?—Decidedly.

1878. (*Col. Harness.*) How do you arrive at any extent of gathering ground which would be above 300 feet?—For this reason, the source of the Gade is 365 feet only above Trinity high-water mark. You mean that you are to draw it from sources 300 feet above Trinity datum; Bury Mill, the second mill upon the Gade, is the first mill which seems to have a constant supply of water, it is only 279 feet above Trinity datum.

1879. (*Mr. Prestwich.*) At what distance is that from London?—In a straight line; I should think it was 23 or 24 miles.

1880. (*Col. Harness.*) Is the Gade the draining stream of the highest portion of the basin?—I do not think there is much difference in the chalk waters. The Kennet delivers itself into the Thames at about 120 or 130 feet above Trinity high-water mark—not more than that—and then you have to calculate how much fall you get to the source, and I do not think that you will get more fall than you do in the Gade. You might get a certain proportion as you go further up. I think that there are none of those streams that you can depend upon, because you cannot depend upon the water; it will not do to go to the upper sources, which are sometimes above ground and sometimes below, you must go to where you can get water at all times. I am sure that you could not get it at 400 feet, and I do not think that you could get much at 300 feet.

1881. Some of those upper streams in oolites are lost occasionally are they not?—Some of those streams are; there is a very remarkable case in the river Churn. One very dry season, I think it was in 1858 or thereabouts, I believe the millers on the stream thought there was some tampering with the upper springs which deprived them of water, and they had a very elaborate and expensive investigation, and it was proved that the river absolutely lost nearly all its water before it got to the Thames, so that you cannot reckon upon it. Where it goes to we cannot say.

1882. (*Mr. Harrison.*) The investigations were made by Mr. Simpson I believe?—Yes. So that you must take the Churn out of the list. I forget now what is the height of the upper level of that canal, the Thames and Severn canal. I am positive that it is not much more than 300 feet above Trinity datum. The height is 330 feet above the sea, or 317 feet 6 inches above Trinity datum.

1883. It is more than that, my impression is that it is about 430 or 440 feet, speaking from memory?—I think you will find the height I have given is correct.

1884. (*Mr. Prestwich.*) You are acquainted probably with springs such as those at Barton at the foot of the chalk hills in the clays and again beyond Ashridge. All of those springs rise at the height of 400 feet above the Thames, and there is another near Hungerford which is also about 300 feet above the Thames. Therefore, without looking to a very large source of supply, a supply of an extent sufficient for the total amount required by London,—is it not possible to find in such springs a considerable quantity of water at a height that will allow that water to be brought to London by gravitation and of a quality sufficiently good for such purposes of supply?—I would not trust to 300 feet.

1885. You consider then that it would be necessary to draw a contour line round the country?—I cannot speak as to the level sufficiently, but my impression is that 300 feet would be too high. I think that you might take 200 feet.

1886. (*Mr. Harrison.*) Even up towards the higher sources you would go a little higher?—Yes, you would find water a little higher, but whether you would find enough I cannot say, on such as you could rely upon.

1887. (*Mr. Prestwich.*) In fact you have not sufficiently gauged those streams or ascertained their height to give a positive opinion?—No.

1888. It would require a complete survey in order to establish those points?—Yes; my impression is that you would find that the most reliable sources after all were in the chalk.

1889. With regard to the quality of the water I

think you spoke of chalk water being very hard ?—Yes, it is hard no doubt.

1890. But you do not consider it an extreme degree of hardness ?—No, there is nothing that I should object to.

1891. Have you compared it with the water from the oolites ?—I think that the oolite waters are more objectionable than chalk waters, but I would rather not speak to that, that is a chemical question to which I would rather not speak.

1892. (*Mr. Harrison.*) You have been accustomed to hard water all your life ?—Yes.

1893. (*Mr. Prestwich.*) As you have always lived in a chalk district and drunk the chalk waters have you ever found any ill-effects from the uses of them ?—Not the least.

The witness withdrew.

ROBERT RAWLINSON, Esq., C.B., further examined.

R. Rawlinson, Esq.

1894. (*Sir J. Thwaites.*) You are desirous, are you not, of adding some little matters to your evidence which you gave to the Commissioners on a previous occasion ?—Yes, some questions were asked at the time I was in the room, with regard to the use and utility of iron service pipes in soft water districts—as compared with lead pipes. I think that Professor Way had not the means of giving an answer to the Commissioners upon that subject so fully as I have if you choose to take replies from me upon that point.

1895. The question arose as to the effect of soft water on iron pipes whether fully charged or upon the intermittent system ?—I am not sure that I gathered rightly that any of the members of this Commission were in doubt as to whether wrought-iron was a proper material to use for house service.

1896. I do not think that any member of this Commission would raise any doubt about it?—There is great doubt, however, expressed by persons outside, iron has been very strongly objected to, and both engineers and architects have repudiated the use of wrought-iron, for several reasons ; first, because they said that it would not stand in use ; secondly, because it was so difficult to manipulate ; and thirdly, that if repairs are required, it is very difficult to repair, on account of its being much more rigid than a lead pipe which can be cut anywhere. I have had an extensive experience in the use of wrought-iron pipes ; it has become, perhaps, almost a mania with me—I will not use lead, and I will not recommend the use of lead. I have supplied with wrought-iron services pipes the towns of Berwick-on-Tweed, Alnwick, Morpeth, Ormskirk, Worthing, Keswick, and Lancaster, and in some of those towns they have been in use 10 or 12 years. The waters of Lancaster and of Keswick are as soft as any waters in the world. The Keswick water comes from the clay slates of Skiddaw, and the Lancaster water comes from millstone grit above Lancaster. Professor Playfair told me that the sample was more like distilled water than natural water, for he had never previously met with natural water so pure. I have not yet heard of mischievous effects of any kind being produced by the use of that water.

1897. How long have the pipes at Lancaster been laid down ?—Ten or 12 years.

1898. Have you examined them ?—No I have not personally examined them, but I have had reports of them, and I think I should have been certain to have heard if they had been disparaged ; I have written for the purpose of knowing how they have stood the frost, as also how they have worked, and I have had no complaints about them.

1899. Have you ever heard of any complaints that the softness of the water was acting upon the iron ?—I think I heard some complaint about a portion of the Keswick pipes, but that was during one summer, when the water was short, and the pipes were alternately filled and emptied during the whole summer, which was a peculiarly dry one, and the source of supply did not meet the demand. Since then we have added to the sources of supply, and I have heard no further complaint.

1900. You account for the action on the pipes by the admission of the atmosphere ?—Yes, if you alternately fill and empty a wrought-iron service pipe, corrosion will be set up.

1901. In your judgment, iron pipes constantly charged with soft water would not be affected ?—Speaking from some years experience, I say they are not affected. Then with regard to their cost they are cheaper than lead, and with regard to their strength they are far stronger, in proportion as iron is stronger than lead. With regard to the facility of fitting them, I have made ordinary labourers into expert fitters. Of course it requires a certain intelligence and knowledge of what you are to do before you commence. The plumbers in supplying a house can bend lead pipes anywhere. In iron pipes there are bends, elbows, and T pieces. A vice, a saw, a file, with taps and dies will give you new screw ends, and you can shorten, lengthen, and turn them round anywhere ; you must put means of escape for air which will accumulate at any up-bend.

1902. When you speak of wrought-iron pipes, you mean the drawn pipes as contrasted with the cast ?—I mean what is known as the best gas tubing. I wish to remark that galvanized pipes are not to be recommended. They cost 40 or 50 per cent. more than plain pipes, and the galvanizing is a delusion. If the pipes are laid in subsoils which will act upon iron, the galvanizing affords no protection against that action, and there are soils which will rapidly eat away either iron or lead.

1903. The galvanized iron is put into boiling zinc or something of that kind, is it not ?—Yes ; but if you examine it under a microscope you will see that it is not an even coating, it is freckled, and there are interstices, oxidation sets up and then the galvanizing is blistered off.

1904. However it would not injure the pipe I apprehend ?—It does not improve it.

1905. And so far as it does cover it it preserves it ?—No, I very much doubt that. It is not stronger in its texture and it certainly does not last longer, that is my experience.

1906. (*Mr. Prestwich.*) When Professor Way gave his evidence, I was under the impression of having read that the waters at Grenoble, where they are very soft, had acted upon the iron pipes and led to the necessity of their all being replaced after a lapse of some 10 or 12 years, but I was not prepared with the exact data or the particulars. Since then I have written to M. Belgrand, the chief engineer of the water supply to Paris, for information upon the subject, and I received a letter from him yesterday in which he refers me to publications where all the details are given, but which I have not yet had time to go into. He, however, informs me that at Grenoble the soft water did produce tuberculous concretions upon the pipes, which led to the necessity of their being removed after the lapse of a few years, and he further says that at Cherbourg the same result was produced ; that circumstance led to a series of inquiries by M. Belgrand and others, and he states that the result of those investigations was that waters chemically pure do not always produce ferruginous tubercles as the first observers believed. Have you information that you can give us upon this subject ?—In Whitehaven soft water from Lake Ennerdale acted on cast-iron pipes, and in a very few years those of small diameter (3-inch) were all tubercled, corroded, crusted up, and filled with oxidised matter, but nothing of that kind has ever occurred in a town that I have had to do with, certainly not in

R. Rawlinson, Esq.

13 March 1867.

Lancaster nor in Keswick. The Whitehaven pipes, I may observe, were laid down without any preparation, whereas I have never used cast-iron pipes without subjecting them to Dr. Angus Smith's process of preservation. The pipe is taken from the sand in the foundry, it is cleaned and fettled, and before oxidation is allowed to set up, it is heated to about 500 degrees, and is dipped into a bath of composition of gas tar, Burgundy pitch, and oil, and I believe a little resin, in certain proportions which are described. Then the pipes are raised up and the surplus matter runs off, and if the operation has been done at a proper heat and under proper conditions each pipe has an exquisite black varnish inside and outside as if it were the finest black paint varnish, and that, I believe, is one cause of success in preventing oxidation from setting up. But there is another point with regard to soft water, which is of far more importance, and that is lead poisoning. Beyond all question of a doubt, and I am speaking now from information which I have received both in Manchester and in Liverpool, lead poisoning has taken place since the introduction of soft water into those two towns, and there are medical men who could give evidence upon the point, Dr. Angus Smith and Dr. Crace Calvert, of Manchester, expert chemists, have had cases brought to their attention.

1907. (*Mr. Harrison.*) Mr. Bateman adopted that plan of varnishing in his Glasgow works, did he not?—Yes, but first of all in Manchester.

1908. (*Col. Harness.*) Your opinion is not that water does not act upon iron but that iron can be so protected that water shall not act upon it?—I have never laid down cast-iron mains without this varnish. Cast-iron mains that have not been varnished, if they have laid five or six months on the ground, become oxidised both inside and outside, and pure water coming in contact with the commenced oxidation carries it on more rapidly. If you lay a varnished pipe six months on the surface it shall not show one particle of rust except where it has been scratched or abraided by rubbing the varnish off.

1909. (*Sir J. Thwaites.*) Have you any experience of the effect of friction upon that varnish, whether it is soon removed or not?—I think not. As the pipe is heated a certain portion of air is driven out from the pores of the iron and then as it cools in the varnish the pores absorb a certain amount of the varnish, which may for anything I know chemically combine with the iron. At all events where we have cut pipes in Lancaster, after eight or ten years service we have found no such blistering as that spoken of at Whitehaven, and as that mentioned in the letter of M. Belgraud.

1910. Would not the flow of the pipe itself be increased by that smooth surface, and the friction be lessened?—I think not. I think that the best mathematicians now know that water flows upon water, and whether the pipe is absolutely smooth or not is not of so much consequence as was once thought if the full diameter is preserved.

1911. (*Mr. Harrison.*) Mr. Bateman stated that in the case of the Glasgow water works he found the discharge from his large pipes very much greater than the ordinary calculation would give, that of course one can quite understand from the fact that all experiments and all formulas are based upon experiments with small pipes, but he also stated this, that since the opening of those works the discharge had been gradually diminishing, is it not probable that that must arise from some alteration in the pipes?—He has some pipes 48 inches in diameter, and it would be a very difficult process to keep those pipes constantly full, as you are aware, water carries in a certain amount of air, that liberates itself and rises to the surface, there are upon all large mains air-valves affixed at up-bends or points to discharge that air; but I have no doubt that a great deal of it plays backwards and forwards, and in parallel mains, if there is much head or fall in the pipes, vaccuums are formed in the pipe by the delivery velocity being greater than the receiving head can take in. For instance, a pipe, say 12 inches in diameter, laid at a grade of a quarter to one, with the delivery under 200 feet head, you have a valve at the lower end, screw it down, and your pipe is full. Open your valve and a gush of water comes out at the first, then it absolutely stops, then another gush comes, and it goes throbbing on for a considerable length of time until friction and gravity have balanced each other, but I believe in that pipe you will find a series of vacuums, that the water is delivering itself by gushes faster than it can get in, and it is the pull upon the vacuum that causes the water to pulsate.

1912. (*Mr. Harrison.*) Have you ever had any difficulty with soft water in reference to your taps and cocks in keeping them tight?—None at all. I insist in all cases upon the wrought-iron pipes having screwed joints and the taps having screw means of fastening, and I require that the tap should be what is known as a screw-down tap, such as those made by Messrs. Guest and Chrimes, Messrs. Lambert, and others, in which all the parts are screwed. You can easily instruct an ordinary labourer, if he is a man of intelligence, to repair such taps. A man would take in his bag or his pocket half-a-dozen three-eighths of an inch taps for cottage service—and a three-eighths tap is quite sufficient, if you have 100 feet pressure, and constant service,—he would screw down his stop tap outside, unscrew the unsound tap, and screw on a sound one. He would do it almost while I am talking about it, namely, leave a sound tap, and take the leaking one home, and there set it to rights. It is generally the leather that has got cut that causes the leaking. The man would repair it at his leasure, and make it a sound tap again. By those means local authorities are enabled to economise water, because when you talk of 20, 30, 35, 40, or 50 gallons per head, you must always consider that you are not talking of supply; you are talking of waste, and the higher up you get in the scale, just in proportion is that waste. I am certain that out of 100,000,000 of the gallons passed into London, 50,000,000 gallons of it are not legitimately used. All over the West End ball taps are deliberately propped up, or taken off, because of the intermittent supply. And, again, I must say that there is very culpable negligence on the part of the water companies; they do not seem to care about wasting water. I can point to places in South Kensington, which I have passed for the last 15 years, where there are stand pipes and valves. I have sometimes seen a channel of waste water that would have filled a three-inch pipe wasting for weeks and weeks together. Whether much or little of that water went through the subsoil and so into the sewers, for the subsoil is gravel, I cannot tell.

The witness withdrew.

Adjourned to Wednesday next, at half-past 11 o'clock.

Wednesday, 20th March 1867.

PRESENT:

SIR JOHN THWAITES IN THE CHAIR.

Colonel HARNESS.
Alderman Sir BENJAMIN PHILLIPS.
THOMAS ELLIOT HARRISON, Esq.
JOSEPH PRESTWICH, Esq.

THOMAS HENNELL, Esq., examined.

T. Hennell, Esq.
20 March 1867.

1913. (*Chairman.*) Are you a civil engineer?—I am.

1914. Are you engaged on any works at present?—I have been assistant engineer in charge of works, and I should be now, but that the works are temporarily suspended.

1915. Are you in charge of any works yourself?—Not as engineer in chief. I am in charge of works as resident civil engineer; as sub-engineer.

1916. Have you ever carried out works on your own account?—No.

1917. Have you ever advised any public body with reference to works of engineering?—No, I have not.

1918. How long have you been a civil engineer?—For nearly eight years; I mean it is eight years since I finished my articles.

1919. You have had your attention directed, have you not, to the subject of the conveying of water to London?—Yes.

1920. In what capacity?—By several of my friends at Basingstoke, who are interested in the Basingstoke canal, my attention was called to the large supply of water they had, which they did not use, and also to the general difficulties of the canal company, and I was asked whether I thought anything could be done for them, and whether any use could be made of the water, and in consequence of that I was led to consider the project of carrying it to London.

1921. What was the result of that consideration?—The result of that consideration is, that I find that 14,000,000 gallons a day for certain can be obtained from the canal, and from sources almost close to it, and can be conveyed to London at a very moderate cost.

1922. (*Mr. Prestwich.*) From what part of the Basingstoke canal could you get those 14,000,000 gallons?—12,000,000 would come from the first eight miles at the Basingstoke end, and about 2,000,000 more from the district of the Bagshot sands between Farnborough and Woking.

1923. Your first district would be chalk?—Yes, my first district would be chalk.

1924. Through what length of chalk area?—I have not taken out the area, because I do not know what the drainage area is.

1925. Through what length of chalk district does the canal pass?—About eight miles.

1926. (*Chairman.*) When you speak of the canal, is it ever used now for canal purposes?—It is used as a canal now, but the company are in very great difficulties. It hardly pays its working expenses, and the company is in chancery.

1927. Your proposal I presume, would be to purchase the interest of the canal company?—Yes.

1928. And to utilize the canal?—To turn it into a conduit for the conveyance of water to the metropolis.

1929. Have you directed your attention to the watershed for the purpose of ascertaining whether it is possible to add to the 14,000,000 gallons?—Yes, I have, I have no doubt whatever that it can be very largely added to. In the first place with regard to the chalk water, I have only taken one-third away from each of the branches of the Loddon, and of course a much larger amount can be taken if proper compensating reservoirs were constructed, or if the interests of the millowners on the river were bought off. Then again with regard to the other parts of the canal, I have neglected the part between the termination of the chalk, which is near Odiham, and Farnborough, because it is all agricultural land, and I imagine that the surface draining would not be worth having; but with regard to the part between Farnborough and Woking, that consists of the Bagshot sands which yield very good water; they are not cultivated, and there is a very large district of something like 20 or 30 square miles which is above the level of the canal, and all the waters of which would probably be collected by proper intercepting conduits.

1930. I suppose you would form reservoirs for the purpose of storing the storm-water, in order to compensate the river for that which you abstracted?—Yes, certainly.

1931. Giving an equal flow to the river from your reservoirs?—Yes, giving an equal flow to the river to what it has throughout the greater part of the year.

1932. If that arrangement were carried out, would it interfere with the interest of the millowners?—I do not think it would. I think they would be relieved from the surplus waters in the flood season, and they would certainly have no water taken from them in the dry season.

1933. They would have water added to them?—They would have water added to them in the dryest season.

1934. What is the discharging capacity of that canal at present?—I believe the springs in the canal and two or three little streams which at present lead into it yield about 3,000,000 gallons a day.

1935. I am speaking of the structural form of this canal; what is its capacity to convey, you say it does convey 14,000,000 gallons?—I say that it can be made to do so, by being turned into a conduit.

1936. Do you propose to alter it?—I propose to form a paved brick channel throughout the whole length of the canal.

1937. Do you propose to increase the size of the canal?—No, I propose to diminish it.

1938. There are a great number of locks, are there not on that canal?—There are 29 locks altogether.

1939. You would be obliged to retain those locks I suppose?—I should get as much fall as would be desirable between the locks. I should not allow the fall to exceed four feet per mile, and that would diminish the height of the locks and the remainder would form a weir.

1940. How do you propose to line it, giving it a four-feet fall?—I propose to adopt several different kinds of section according to the amount of fall to be obtained at different places. Here is a section with two or three specimens which may be adopted in different parts (*producing the same*).

1941. Do you line it with brick?—With brick paving on concrete, taking 9 inches of concrete as an average.

1942. What in your judgment would be the utmost extent of water which could be fairly calculated upon to be obtained from that area?—Supposing the whole were taken from the Bagshot sands, as mentioned in the reports of Mr. Bateman and other engineers in 1852, I believe there are about 7,000,000 gallons to be obtained there.

1943. That is in addition to those 14,000,000 gallons which you have already mentioned?—Yes, in addition to the 14,000,000, and with regard to the chalk water, I imagine that amount might be increased; it is entirely a question of compensation to the millowners. If the whole were taken from the river it would amount to about 30,000,000 gallons instead of 12,000,000.

1944. Do you know the number of mills on those streams?—I do not know the number, but I can count

T. Hennell, Esq.

20 March 1867.

them if it is desired; they are all shown on the Ordnance map.

1945. They are very numerous, are they not?—Yes, there are a very great many.

1946. That would make 21,000,000 gallons which is a very small portion for the supply of the metropolis?—I only propose this as a scheme in extension of the present system of supply, that is all.

1947. (*Col. Harness.*) Where is the summit level of the Basingstoke canal?—The head springs are at Greywell about six miles from Basingstoke.

1948. What is the summit level of the canal itself?—There is one long reach from Basingstoke to Aldershot, and the whole of that long reach forms the summit level.

1949. Do you remember what is the level of it above high water?—It is 252 feet above Ordnance datum at Basingstoke.

1950. (*Chairman.*) Have you made any estimate of the probable cost to purchase the canal?—Yes, that I have done, and I should just mention that in the statement in the hands of the Commission I put down 260,000*l.*, which included everything but the purchase of the canal. I had not the means at hand at the time of supplying that, but I have been able to do so now. I put down 20,000*l.*, and I have good reasons for adopting that sum for the purchase of the canal, and 260,000*l.* for works.

1951. Where does that canal terminate?—It joins the River Wey, near Weybridge.

1952. Then there would have to be a conduit?—Yes, then I should have to convey it eight miles to the existing reservoirs at Thames Ditton.

1953. And that is included in the 260,000*l.*?—Yes, and that I propose to do by a covered channel.

1954. That should be in tunnel, I presume?—Yes.

1955. Above the surface or what?—For a short distance opposite Weybridge where there is a very considerable hill it would be in a cutting varying from 20 to 40 feet deep for about two miles, for the remainder of the distance it would be just below the surface.

1956. (*Col. Harness.*) What is the level of the basins at Thames Ditton, where you propose to take it?—The level of the river.

1957. To whom do the basins belong?—They belong to the five water companies, who take their water from the Thames now.

1958. (*Chairman.*) Does that 260,000*l.* include the reservoirs for compensating the rivers?—It includes the compensation and storage reservoirs.

1959. Have you any section of the reservoirs?—I have a plan of the largest reservoir, with the levels from actual survey (*producing the same*); 112 acres is what I have taken, and 40 acres is shown on the plan as a possible extension.

1960. What rainfall have you calculated as being due from this area?—I have not taken the chalk waters by rainfall at all.

1961. The plan that you have put in shows a section of your embankment, and also the area of your reservoir, amounting in all to 112 acres and 40 acres. The holding capacity, I presume, would be 840,000,000 gallons?—Yes.

1962. And 250,000,000 gallons would be that of the 40 acres?—Yes.

1963. What depth is your dam?—43 feet is the height from the ground to the surface of the water, and the bank would be four feet higher.

1964. Do you make one part of clay puddle?—Yes.

1965. Of what is the other portion constructed?—The other would be constructed of a material which is a mixture of loam and sand. The whole reservoir would require lining.

1966. How do you line the surface?—The surface would be lined with puddle about one foot in thickness. I have allowed for that. There is a mixture of sand and clay, and possibly it might not be required to be lined throughout.

1967. Do you know of any embankment of this character and height formed with a material of that loose porous description?—I do not know of any, but it is a material that stands at a very good slope on railway cuttings.

1968. You give it a slope of 3 to 1, do you not?—Yes, on the inside.

1969. But supposing the water were to break your lining, through the clay into the sand, what would be the result; would not it blow up?—I suppose the water would find its way through gradually, if it did break the lining.

1970. (*Mr. Prestwich.*) The water would all escape in that case?—The lining, of course, must be made perfect; it would depend upon that.

1971. Are there no materials in the neighbourhood of which this could be made without having resort to sand?—There is clay to be obtained within four miles of that spot.

1972. That would add very much to the cost, would it not?—Yes, if the whole embankment were constructed of it, of course, it would add very much to the cost.

1973. Have you no stone of any kind in the district?—There is no stone there.

1974. What is the extent of the drainage area of the gathering ground?—As far as the chalk is concerned, I have taken it from the gaugings of the springs. I believe that the rainfall is 24 inches, but I have not founded my calculations upon that.

1975. Have you gauged the streams running from that district?—Yes.

1976. What is the net result of that in inches of rain?—That I am unable to give, because I have not taken out the area of the gathering ground. I do not know where the springs come from. I could not draw a line so as to say what particular ground supplies particular springs.

1977. But you know where you expect your water to come from?—The water comes from the springs which issue on the margin of the chalk for eight miles.

1978. And these depend upon the rainfall?—Yes, that is dependent upon the rainfall on a very considerable extent of country; but it is impossible to say exactly what extent.

1979. How do you calculate that you will get this 840,000,000 gallons of water?—840,000,000 is 60 days' supply at 14,000,000 gallons a day.

1980. That is the supply for your conduit?—Yes, the 14,000,000 gallons consist of the 12,000,000 gallons from the chalk that I have obtained by gauging the actual springs themselves, and 2,000,000 are from the sand district.

1981. Have you gauged the streams?—Yes.

1982. You have calculated the annual rainfall at 24 inches, I believe?—I have not founded my calculation upon that, but I believe that is so.

1983. Having regard to the gaugings that you have made of the several streams, what depth of rainfall would that account for?—To answer that question I must know what the area is from which the springs are supplied, and that I have no means of getting, because there is a large extent of chalk hills, and there are springs on one side of that range of hills, and there are springs perhaps 8 or 10 miles off on the other side, and I cannot draw the line so as to say which part of the country supplies the springs on the one side or the other.

1984. Then your attention has been directed rather to the springs than to the gathering ground that would feed those springs?—Yes.

1985. You are not able to state to the Commission what the amount of evaporation or what absorption of rainfall would be?—No.

1986. (*Mr. Harrison.*) Referring to your section of course, the height and slope of the embankment would depend upon the material of which it is made?—Yes; there is only a very short extent of that deep bank, about eight chains; around the rest of the reservoir the general height of the bank is 10 feet.

1987. Those waters now all flow into the Thames, do they not?—Yes, they do.

1988. Therefore your proposal to intercept at their source the waters that now flow into the Thames, would in effect be merely taking water from the Thames?—That would be so no doubt, but at the same time there is a very great loss of water in the canal itself. It leaks at almost all the embankments, and the greater part of the water so leaking gets on to the land, and is lost by evaporation in a very great measure.

1989. Still your project may be taken simply as a plan for taking the water at its source before it flows into the Thames?—Yes.

1990. But still adding to the quantity that is now taken from the Thames, the water that you bring to the general reservoirs, and there mixing it in a purer state with the existing water of the Thames?—I hardly suppose that the same reservoirs would be used, but other reservoirs in the same place.

1991. But with regard to distribution, you propose to distribute this water, do you not, by the same pipes, and, therefore, the waters will become mixed in that way?—Yes; but then I take the water in the flood season, and the existing companies take the water from the Thames when they want it.

1992. It comes to this, that you would merely propose to introduce a certain amount of water in a purer state than what it may be taken to be in the Thames, and to mix it for distribution with the present supply from the Thames?—That would be so if this scheme were taken up by the existing companies at Kingston, but the mixing of the water would only take place if it were divided between several companies. There are at present five companies distributing on the average about 10,000,000 gallons per day each; the proposed supply of 14,000,000 would be an ample supply for any one of them to use exclusively, and, if extended as suggested, might in like manner be made available for any two.

1993. You do not propose to have a new system of distribution for so small a quantity of water as your scheme would supply?—I have not proposed that, but it is possible of course that it might be done; and as one instance, I may mention that there is a company this year who have deposited a scheme for making a reservoir within a short distance from the Thames, and taking a fresh supply; and that company or any other company similarly situated might take the whole of what I propose to bring there, and leave the Thames alone.

1994. Still the distribution would be by means of one of the existing water companies?—Yes.

1995. (*Mr. Prestwich.*) Have you had these waters tested or analysed?—No, I have not. I have no doubt that they are very similar to the other chalk waters of the same district. The Farnham branch of the river Wey, which rises about eight miles from some of the sources which I have mentioned, is of 14 degrees of hardness.

1996. But you propose, do you not, to take water not only from the chalk, but also from the Bagshot sands?—A small quantity from the Bagshot sands.

1997. Therefore the mean of the water would be less?—Yes.

1998. And that you would obtain probably by the waters in the canal as it passes through that district?—Yes.

1999. You say that from Basingstoke to Aldershot the canal maintains a uniform level, and that there are no locks?—Yes.

2000. Consequently, at Aldershot, you are at a distance of about 30 miles from London, at height of 250 feet above London?—That is so.

2001. Therefore the water might be brought to London by other means than by the culvert which you propose, or bringing it along the canal, and be delivered in London at a very much higher level?—Certainly it could.

2002. (*Mr. Harrison.*) Taking the distance as 35 miles, what should you consider to be the necessary fall per mile through those pipes in order to overcome that friction for distribution, at a height, say of 200 feet, in London?—That would depend upon the amount of the piping. If it were an open channel, such as I propose to make, and the country would allow of an open channel for a considerable part of the length, it could be done with a fall of six inches to the mile for that part.

2003. Your plan, as I see by the section, is to come directly down into the valley?—My plan is to make use of the canal, undoubtedly thereby losing a certain amount of power.

2004. (*Chairman.*) As I understand, you propose to discharge your water at the level of the Thames, at Thames Ditton?—Yes.

2005. (*Mr. Harrison.*) Therefore it would have to be pumped up again for delivery in London?—Yes.

2006. (*Chairman.*) As a practical question, you are intercepting the waters at a higher point, and bringing them so many miles to Thames Ditton, instead of allowing them to flow into the Thames and become polluted, as the present water is, and to give auxiliary aid to the several companies at that point?—Yes.

2007. And there the waters must be mixed with the other waters of the Thames to supply the metropolis?—Yes, or used by one or two companies only.

2008. (*Col. Harness.*) Where do the Canal Company derive your waters from now, from the supply of the reach at the summit level?—From springs in the neighbourhood of Greywell.

2009. What quantity of water can they supply?—They supply, as far as I have been able to ascertain, about 2,500,000 gallons per day.

2010. Do the Canal Company receive it into the reservoir and store it?—No, they do not.

2011. Do they draw it into the summit level as it is wanted?—Yes, they draw it as it is wanted; they have sluices at different places to let off the surplus.

2012. (*Mr. Prestwich.*) Besides those wells at Greywell, do you consider that the canal intercepts springs between Greywell and the point where it leaves the chalk district?—Yes, it does; it intercepts the principal source of the rivers Loddon and Whitewater.

2013. Have you any knowledge of the quantity of water that is delivered by those springs?—Yes, I have. To take first the Whitewater; that I found in October contained, in round numbers, 10,500,000 gallons. I propose to take one-third of that, and that is rather the largest of the three principal sources.

2014. Where is this?—That is the river Whitewater, which is almost close to Greywell; it rises about half a mile above Greywell, and it discharged 10,500,000 gallons on that day in October, of which I propose to take one-third. I measured the stream again last week, and I found 14,500,000 gallons daily. Then, in addition to that, there are the Mapledurwell and the Newram springs within a mile of Basingstoke.

2015. Can you state the volume of those springs?—The Mapledurwell springs contain 1,980,000 gallons. There are springs east and west of the village; those which are on the east side of the village I cannot conveniently take, because they are at a low level, but they unite afterwards, and therefore I take two-thirds of the western springs only, which would be equal to one-third of the whole. They unite before they come into any stream where they would be required, and therefore I take two-thirds of 1,980,000, that is 1,320,000. Then the Newram springs contain, in round numbers, 4,500,000, of which I take two-thirds; that is 3,000,000.

2016. What is the total quantity of all those springs?—The entire total is 28,296,000.

2017. Does the canal intercept springs at the level of the canal?—Yes.

2018. Therefore the water would flow into the canal in all those cases?—Yes.

2019. (*Chairman.*) Have you made any estimate of your works?—Yes.

2020. Can you hand it in?—Yes, I shall be happy to do so.

T. Hennell, Esq.

20 March 1867.

The witness delivered in the following paper:

ESTIMATE.

	£		£	s.	d.
Adaptation of Canal:					
Newram springs to Greywell tunnel, 4½ miles. Section No. 1[a]	1,400	per mile	6,300	0	0
Greywell tunnel to Aldershot, 13¼ miles. Section No. 2	2,801	„	37,113	0	0
Aldershot camp, 1½ miles. Covered section	6,160	„	7,700	0	0
Aldershot to Frimley lock, 5⅝ miles. Section No. 3	2,530	„	13,598	15	0

2021. (*Mr. Prestwich.*) What you have stated has been with regard to the chalk, have you any knowledge of the delivery by springs into the canal from the Bagshot sands?—No, I have not. I have taken that as an approximation from the rainfall.

2222. Does not the canal pass through the Bagshot sands above the level of the delivery of the springs?—I should say perhaps above some, but certainly below the greater part of them.

2023. Can you tell me anyone which is above the level of the canal?—The canal at Frimley Ridge is above the level of most of the springs, but in other parts (*pointing them out on the map*) and especially where I propose to place the reservoir, it is below them.

2024. Do they all pass below the level of the canal?—The Cowshot spring passes under the canal.

2025. The canal at that point is upon a much lower level, is it not, than it is at Aldershot?—Yes.

2026. Therefore in the first long reach between Basingstoke and Aldershot you could hardly depend upon anything beyond the delivery from the chalk?—No, I do not depend upon anything else.

2027. What is the exact position of the reservoir in respect to Pirbright?—It is partly in Pirbright and partly in Woking parish.

2028. At that spot do you know what thickness of sand you have beneath the bottom of the reservoir?—No, I do not know that.

2029. Are you aware that the sands there are 100 feet thick?—I was not aware of that.

2030. (*Col. Harness.*) There is a large collection of water, is there not, between Basingstoke and Aldershot, which the railway crosses?—That is Fleet Pond.

2031. What feeds that pond?—That is fed in great part by the escape of water from the canal when it is let off from the sluices, but not entirely so.

2032. (*Mr. Prestwich.*) Might you not near Aldershot itself have a more favourable position for the construction of a reservoir for such portion of the water as would be derived from the chalk?—I am afraid not unless a new conduit were made from that reservoir down into the canal further on, because there is another reach of five miles below the Aldershot lock; and any reservoir to have any depth would necessarily be below that level.

2033. Do you know the height of the London clay in that district?—No, I do not.

2034. Does it not come very nearly to the level of the canal?—I should think it did.

2035. Those springs from the chalk I think you state you have only gauged within a comparatively recent period?—Last autumn.

2036. From your knowledge of that district do you believe that those springs maintain their permanent character for the greater part of the year?—They do not vary very much. Of all the sources which I have taken here there is only one, a small stream which yields 500,000 gallons, which I did not mention just now, that ever runs dry; all the rest are constant and remain tolerably even.

2037. I see that the total quantity that you estimate to collect at Pirbright would be equal to 14,000,000 gallons daily?—Yes.

2038. How much of that do you propose to derive from the chalk, and how much from the Bagshot sands?—12,000,000 from the chalk, and 2,000,000 from the Bagshot sands.

2039. In the 12,000,000 from the chalk you have shown that there are springs existing that would furnish that quantity, but you are not able to furnish the Commission with evidence as to the instance of any springs with respect to the additional 2,000,000 from the Bagshot sands?—The Cowshot stream which I pointed out just now is the only one that I gauged, and that I found contained 500,000 gallons, but it would appear from the map that that would only be one of several.

2040. But independently of that source you calculate upon 12,000,000 gallons?—Yes.

The witness withdrew.

GEORGE HAMMOND WHALLEY, Esq., M.P., examined.

2041. (*Chairman.*) You have turned your attention, have you not, to the question of the water supply for the metropolis?—Yes, generally to the water supply of the metropolis, and also of other towns that may require a supply of water.

2442. I understand your gathering ground would be in Wales?—Yes. My attention was called to the subject by the publication of the scheme of Mr. Bateman, for the supply of water to the metropolis. That scheme presented as a gathering ground a large district in Wales with which I am connected, as the owner of land in the neighbourhood, and I gave attention to the subject in order to see how far it would affect myself as a landowner. The result of my inquiry was that so far as withdrawing the water from the rivers of that district, it appeared to me that no persons, whatever their interest in the existing streams, need feel apprehension as to the result of Mr. Bateman's scheme, for without being enabled to express a professional opinion upon the matter, I felt I was justified in assuming, by the communications I had with Mr. Bateman, that he would be prepared to show by figures that the storing up large quantities of water, and supplying it as he proposed, could be carried out without injury to existing interests.

2043. He proposes, as you are aware, to compensate the rivers for the water which he abstracts by storing the storm waters and equalizing the flow of the rivers?—That was the point to which I directed my attention. From knowledge of that district, I felt satisfied that an enormous quantity of water could be so stored, not only without detriment to the regular flow of the rivers for mills and other purposes, but with great advantage to property in the neighbourhood of those streams by the prevention of floods. I went into the matter very fully, both by myself and also in conjunction with other landowners, and we came to the conclusion that the result of his scheme would be, with proper precautions, that while there need be no detriment to any interests now affected by the existing streams, whether fisheries, or mills, or landowners, there would be a benefit conferred upon the entire district by preventing the heavy floods to which that district is liable, and which involve landowners in annual expense, very much increasing in recent years. We attribute that increase principally to the operations of the Enclosure Commissioners and the facilities afforded to landowners for draining. Very large sums have been spent in artificial draining, and the effect of that draining appears to be to prevent the water flowing down to the reservoirs provided by nature, and from which the springs are supplied, and pouring all at once into the open channels of the country.

2044. When you speak of that district, do you mean that the district forming part of the gathering area suggested by Mr. Bateman is drained in the manner you have described?—The district to a great extent is mountain land, and no plough has ever been over it. Perhaps for a distance of say 100 miles in length, it is chiefly sheep pasture, ranging from 30 to 50 miles in breadth towards the west coast of Wales.

2045. I think you state that you have suffered from floods?—Yes, and increasingly so. The first impression throughout that country was that the effect would be to carry the rivers bodily, as it were, to London, and to create losses, and to interfere with great interests as regards fisheries, and mills, and so forth, but when we looked into the matter with more care we became satisfied that the scheme did admit of such precautions, and that Mr. Bateman seemed to be prepared to take such precautions as would obviate those difficulties, and might confer the benefits I have suggested.

2046. Have you had any meeting of proprietors in that district to discuss the effect of Mr. Bateman's scheme upon your property?—Not exactly a meeting of proprietors, but I have had more than one meeting in the town of Llanidloes, which is the first considerable town upon the river, and the town that would be immediately affected by such a scheme. We have had meetings there, and I brought my views before them to the effect now stated that it would be a benefit to the town in many respects, and those views were adopted, and the public felt disposed to do all in their power to afford a fair investigation of the scheme.

2047. You are well acquainted, are you not, with the whole of the area proposed to be dealt with by Mr. Bateman?—I know two or three parts of the area, and I think I may say I am well acquainted with it, as I have had a great deal to do with railways there.

2048. Confining your observations to the gathering area suggested by Mr. Bateman from your knowledge of that district, are you able to state to the Commission whether there are any lead or other mines, and if so, what number within that area?—There are no mines excepting lead.

2049. Are there no copper mines?—I am not aware of any. Sometimes in lead mines you find some small amount of copper, but I am not aware of any copper mines. The mines of that district are, to the best of my belief, confined to the lower portion of it, in the neighbourhood just above Llanidloes, on the slopes of Plinlimmon.

2050. Are those mines in working now?—Some of them are.

2051. Are they extensive?—They vary. It is a precarious district for working lead mines, as compared with the district further west, towards Aberystwith and in Cardiganshire.

2052. But those mines are not in this area?—No, they are not in this area of Mr. Bateman's.

2053. Have you observed the effect of the workings from those mines flowing into the rivers?—That is one of the points to which I have directed my attention. To support a scheme for the supply of water to London or other places would, of course, imply that the existing streams must be kept pure, and the owners of property containing lead would find themselves in a serious position if they were prevented, in consequence of a scheme of this kind, from working their mines. Therefore I gave attention to that subject, and the result of it was to satisfy me that there was no necessity either in the interest of the landowners or of the workers of the lead mines that the water required should be affected by such a scheme. Amongst other means that I took to satisfy my mind upon that subject, I visited a large mine worked by Messrs. John Taylor & Co., called Pant Mawr, about seven miles above Llanidloes. The washings from that mine had formerly been found to be very injurious to the fish in the river, and I called the attention of Mr. Taylor to the matter. With great liberality he gave the necessary orders, and the result of it was that the fish returned to the river, and the means he adopted was simply to increase the number of slime pits or settling pits. On a visit that I paid to those mines, I think in November last, they were working the mines, and the water was at that time running from those slime pits into the river, and within a few yards of the outfall of those slime pits small fish were to be seen in the river.

2554. Did you observe that in those pits any ingredient was used for the purpose of precipitating any of the matters held in suspension, or were the waters allowed simply to settle and pass through a series of pits?—I am not aware that there was any means adopted, except increasing the number of the pits.

2055. The water run off comparatively pure, I suppose?—Yes.

2056. You do not know whether it held anything in solution?—There were suggestions about a sulphuric element, or something of that kind; but I am not qualified to speak to that.

2057. The fish returned to a higher point than they reached before?—Yes.

T. H. Whalley, Esq., M.P.

20 March 1867.

2058. And you attribute to results of this scheme the purifying of the water from pollution?—Yes.

2059. And do you think that principle might be adopted elsewhere?—I do not see why it should not; I live in the neighbourhood of Ruabon, within a few miles of the largest lead works, I believe, in the kingdom. The largest returns of lead are yielded from the mineral district between Ruabon and Wrexham.

2060. As a landowner in the district have you yourself, or have you in connexion with other landowners, discussed the question as to this area being reserved as a gathering ground for the supply of water to the metropolis, and what the effect would be on your mineral property?—I have not so discussed the matter with other landowners, as to justify me in expressing their opinions.

2061. You have lead, have you not, on your property?—I have none worked there, but it is supposed to contain lead. There have been from time to time explorings, and so forth.

2062. If you were selling the land, you would not hesitate to state that there was just that chance of finding minerals there?—Undoubtedly it is a highly mineralized district. For instance, at one extremity of my property there are mines called Cwmystwith, and on the other side some mines called the Delife mines. Both of them are most productive mines, and have been so, especially the first mentioned, for many centuries. In the opinion of competent persons, the veins run intervening between those mines, and would run through all that property.

2063. Supposing this scheme of Mr. Bateman's were so ripened as to come before Parliament, the question for Parliament to consider would be, first, as to the gathering ground, secondly, as to the quantity of water that it would yield, and thirdly, how that gathering ground could be preserved from any source of contamination for the future, and certain prohibitory clauses might be introduced into a bill, that the owners of lands should not open mines here, there, or elsewhere, so as to pollute the streams which ultimately find their way into those reservoirs. What would be your view of such a piece of legislation; would you still think that Mr. Bateman could be a great benefactor to the district by carrying out his scheme, or would you think it an interference with the rights of property?—Putting it in that way, it would materially interfere with the rights of property; but I am acting upon the assumption that having regard to the importance of the public demand for water, there would be means adopted to afford protection to the landowners for such interest as might be unavoidably interfered with.

2064. But would you as a landowner be prepared to submit to prohibitory clauses restricting the exercise of your rights over the property, and requiring that you should not open a mine at point A. B. or C., because the result of that working might contaminate the water?—I should not, in the state of my present information, be prepared to submit to such a clause, nor should I think such a clause necessary, because in a case in which I had occasion last year to obtain a bill for the supply of a small district in my own neighbourhood, the water which came from my own land, and from a district which is not only mineralized by lead works but also by coal and ironstone, I consulted my solicitor with regard to the protection necessary, and he told me that the General Water Clauses Act would afford sufficient protection. I am not assuming that landowners would consent to be deprived of any powers that they now possess over their land; I merely express an opinion that it being put upon the principle that they were not to be injured, either they would not be injured, or if they were injured they would only be injured to so moderate a degree as that a scheme of this kind would provide the means of compensating them.

2065. Do you think that Parliament would consent to an expenditure of 10,000,000*l.* or 12,000,000*l.* to carry out those large works, the object of which would be to convey to London the water gathered from that district, without at the same time protecting that water from pollution by prohibiting certain things?—I have never considered it in that way, because I do not think that Parliament will sanction such a scheme as Mr. Bateman's, and if my plan is adopted I do not think it necessary that they should do so.

2066. You are aware that one of the propositions that is placed before the Commission is to gather the water in that district and so bring it to London?—I had an interview with Mr. Bateman, and suggested to him that instead of involving the country and the metropolis in the expense which he proposed, and the delay which must take place in accomplishing his object, he might adapt his scheme somewhat in this way, to afford facilities to the landowners who might happen to have water rising in or flowing through their lands, and also lands readily convertible into reservoirs to make such reservoirs; also to afford facilities to the railway companies which now penetrate that district to convey that water from those reservoirs by pipes along the course of the railway, thus obviating the necessity of great engineering works and so forth, and also to afford facilities for existing water companies either in the metropolis or elsewhere to purchase the water so conveyed. I subsequently ascertained that such facilities would be, I think, eagerly seized by landowners in that and other districts with a large extent of mountains and with a most perfect water. I also found by communication with the Great Western Railway Company, and at the time being chairman myself of railways in the district, that we should be most happy to convey the water, I think I may almost say for nothing, in consideration of the great advantage which the railway companies would derive from having the command of water of such extreme purity and softness for the use of their engines; of itself a very great advantage and saving in many cases to the railways. I found that the London and North-western Railway Company had already carried out between Crewe and some districts in that part of the country something like the scheme that I am now suggesting; that is to say, storing water and conveying it along their line for the use of their engines.

2067. I suppose it was to be carried by means of iron pipes?—Yes; I also found by communication with a gentleman recently returned from India, that a scheme of that kind had been carried out with extraordinary success for carrying water a distance of 50 miles to Bombay by a pipe from five to six feet in diameter, along the railway, and that the effect of that had exceeded everybody's expectation; it had diminished the deaths in Bombay by something like one-third. He had no doubt, nor in fact have I heard any doubt expressed by the persons connected with railways who have had any means of forming an opinion that there would be any practical difficulty in conveying along the railways the water that might be so stored up in the way I have suggested. As this would be done by the landowners, for their own benefit as a means of making the most of the resources of their property, they would take care that the water was kept pure and thus meet many of the difficulties now suggested of that nature.

2068. Then I understand your proposition to be this, that the landowners in the district should have the control of their own water, that they should gather from their own ground, or unite together for the purpose of gathering from a large area water in one reservoir, and become wholesale dealers in water, supplying any company that might bring up their pipes to the place where you have gathered your water?—Yes; that expresses my views quite accurately.

2069. You state that you had some communication with the Great Western Railway Company; was it with a director or with the chairman?—No; with Mr. Grierson, the manager. I have not been in a position to ask him for an authoritative opinion, but I stated that I was obtaining information for the purpose of bringing it before a public meeting in

Llanidloes, and consulted him whether he could suggest any practical difficulty in carrying out such a scheme, and his reply was that he could not, but on the contrary, it appeared to him a feasible mode of conveying water by means of pipes along railways; either one pipe or many pipes; and he referred to the fact that there was a scheme before Parliament some few years ago for bringing salt water from Brighton to London for bathing purposes, and that it passed so far as any engineering or railway difficulties were concerned, and that there was no practical objection suggested to it.

2070. (*Mr. Harrison.*) One object would be to deliver the water in London at such a height that there might be a constant high level service. If your idea is carried out that you are to convey it through pipes there is no doubt that the fall per mile in the pipes would be a great deal more than you would require for carrying it in a mere open conduit, and, in fact, if there was any great extent of pipes to be used in the length of it it would do away with that object which is the essential one to be obtained?—That is an engineering question. I had some discussion with Mr. Bateman upon the subject at the Social Science Congress at Manchester, and I think that that was his difficulty. I urged upon Mr. Bateman the abandonment of his scheme in favour of free trade in the supply of water or that he should proceed with his scheme at once. His reply was that in the first place he was too much engaged to give attention to the matter for this present session, and in the next place he suggested the difficulty which you have now pointed out, that he could not by means of pipes along the railway maintain the requisite elevation.

2071. If you were going to carry it by pipes all the way, you could not by possibility bring it to London at a high level, you must have a greater fall through the pipes than by carrying it in conduits?—That is a matter upon which an engineer would speak better than I can. You are aware that Llanidloes is the highest corporate town in the kingdom. I consulted various towns on the route; the towns of Builth and other small towns that are in very great want of water, and I found that the laying of pipes of this kind along the railway would be found highly remunerative in the supply of water to all those intermediate places, and that they would be enabled to pay a considerable sum for the water which could be so supplied to them, rather than be subjected to the expense which many of them are contemplating of constructing independent reservoirs; that, in fact, the railway would be one continuous reservoir for every town and every kind of works, including the railway company's service.

2072. Are you aware that the cost of conveying it by pipes per mile would be largely in excess of what it would be to carry it in an open conduit?—Of course I must leave that question entirely to the engineers; but it does not follow that all the water must be brought by one route, as in the case of an open conduit, such as Mr. Bateman's, one railway will bring one supply and others the like.

2073. (*Chairman.*) Pipes would be a necessity, would they not, if it were brought by rail?—Yes.

2074. (*Mr. Harrison.*) It would be infinitely more expensive, would it not, than the plan proposed by Mr. Bateman, of bringing it partially in conduits and partly by pipes?—I can hardly imagine that. It has been done frequently in other cases. I can mention a case where it has been done at Tenby, to which the water is brought from near Pembroke.

2075. There they have got an abundant fall, have they not, and a head of water which enables them to use a much smaller pipe?—I am not aware of all the circumstances of that case.

2076. You are pretty well acquainted with the Vale of Llangollen, are you not?—Yes.

2077. Taking the Bala Lake and the whole of the district there, I suppose you look upon that as one of the finest supplies in the whole of North Wales?—Yes, Bala Lake is just an illustration. It happens to be a natural lake, but I believe that anybody who went over this district from Bala Lake would find in plots of 50 100, 200, and 500 acres of land that might be converted into lakes similar to Bala Lake, and at a comparatively trifling expenditure with thousands of acres of gathering ground around them which has never had a plough upon it, and seems exactly adapted by nature for the purposes of a gathering ground.

2078. (*Chairman.*) Have you formed any opinion in your own mind as to the price at which landowners would be prepared to sell their water?—No, in the instance that I referred to of supplying water to a district in the parish of Ruabon, that question was put to me. I referred the matter to competent persons, at Liverpool—engineers and other persons—and the result has been, that they agreed to pay a royalty to me of one-tenth of the gross receipts that the company will receive from the supply of water. That was settled in that instance, and, I believe with general approval.

2079. You are aware, are you not, that you have no interest in the water beyond what is due to the supply of your estate; that is to say, if you intercept water which has from all time run into a certain channel either utilised for mill purposes or otherwise, any interception on your part would involve compensation to the parties below you?—Of course.

2080. If you catch water because water falls upon that area it does not follow that you have any vested interest in that water and that you should deprive others of their natural rights?—No; but that is a different state of things to conferring upon other persons a vested interest in the surface of the land, for instance, laying pipes, or storing and so forth, it is giving a service over the land, which may prevent buildings and many things to which the land might be applied.

2081. I think your suggestion might be taken generally to be quite at variance with the principle which is adopted by water companies generally; their plan always is to buy the fee simple of the land upon which their reservoirs are placed. I am not aware of any case excepting the one you mention in which what may be called a royalty for water has been paid?—In this case the option was given to the company either to pay it in that way or to pay at once 1,000*l.* for the land, which included several acres of land.

2082. (*Sir B. Phillips.*) Did I understand you at starting to say that as far as Mr. Bateman's scheme was concerned, you thought it would be very beneficial to the landowners in your district for the purpose of preventing constant floods?—I think if carried out as proposed, it would be so; that is my opinion.

2083. Then as far as that goes you approve of Mr. Bateman's scheme?—Certainly.

2084. Then you subsequently say, do you not, that as far as the public is concerned you disapprove of it?—As far as the delay and the cost were concerned, great objections occurred to me.

2085. Of course it could not be carried out without delay and cost?—By the scheme that I suggest you might have a supply from those mountains in six months. I should suppose it would be very easy to lay a pipe the whole distance and at very much less cost than Mr. Bateman's scheme.

2086. (*Chairman.*) What I understood you to say was this: that Mr. Bateman proposes to abstract from the rivers a certain amount of water, and to compensate for the river water so abstracted by reservoirs storing the storm water, and thus not to injure the rights of the millowners on the stream or any parties having rights below the point of abstraction?—Certainly.

2087. And then, with regard to your own scheme, you have stated that is just what we landowners could carry out; we could make our arrangements; we could construct those reservoirs; we could store a sufficient quantity of water to compensate those rivers for what water we are taking, and we should, therefore, not be liable to compensation to millowners, and we should constitute ourselves large wholesale dealers in water, and be prepared to supply

T. H. Whalley, Esq., M.P.
9 March 1867.

any company that will bring their pipes up to our ponds?—Yes.

2088. (*Col. Harness.*) Do you believe that you could carry that out without an Act of Parliament?—In the first place, without an Act of Parliament you cannot protect yourselves against the polluting of the water above, and, in the next place, you are left entirely at the mercy of millowners or anybody else who may be on the stream below. Again, landowners cannot, as a general rule, find ready money to carry out those schemes. Parliament has already interfered to assist landowners to make the most of their estates by means of draining and fencing, and so on, giving to those who may be interested in the reversion, or the mortgagees, such protection as can be given by an examination by the Enclosure Commissioners, and a certificate that the expenditure will be a permanent benefit to the estate, so that the reversioners will not be injured. I think it reasonable that the same principle upon which that has been allowed, and is daily practised with regard to drainage should be extended to developing estates with regard to storing up water.

2089. (*Colonel Harness.*) That point would of course only be applicable in case you require to borrow public money for the purpose?—Yes, of course. You can either borrow public money, or you can advance money as it were to yourself; that is to say, the money that is so spent might take precedence over all previous charges, such as mortgages and reversions and so on. Then the next point that you would require is, that a landowner who should go to the expense either by borrowed money or by his own money to enclose say 100 acres of land for a reservoir or to make a Bala Lake or something of that kind, should be enabled to protect that lake against the water being polluted above. Then a third matter, and one of very great importance, is that there should be some means of readily ascertaining the amount of compensation to be given to millowners and other persons who may apprehend damage below. For instance, in the case I referred to in Ruabon for many years past an impediment to carrying out a scheme of that kind has been a tumble-down good-for-nothing old mill, which was on the lower part of the stream. No power could get this man to agree to any terms; we had no means of ascertaining his loss, he would not tell us; he would not take any reasonable compensation, and, in fact, there was no dealing with him. A clause has been introduced by Lord Redesdale whereby we agreed to provide him with the same quantity of water out of our storage as he has at the present time for his mill, and that the mill should not be in greater want of water after those works are carried out than they were before, with the option of paying him for all his rights the sum of 450*l.* That, practically, was the way that we dealt with him. Then, according to my plan, if we spend 5,000*l.* in enclosing the land and making a lake that 5,000*l.* will so add to the value of the estate that persons would be found willing to advance money upon it.

2090. (*Chairman.*) There is no doubt, I think, that you require statutory power for that purpose?—Yes, that would be so. The bill which I sent to the honourable chairman explains exactly what I propose.

2091. (*Mr. Prestwich.*) Does cultivation extend much in the area marked on the map as the drainage of Mr. Bateman?—Very little; it is almost entirely mountain; and I should think it is quite a fractional part just down in the valleys.

2092. You stated, did you not, that the floods were increasing from year to year in consequence of the improved system of drainage?—Yes, in the lower part of those valleys.

2093. It is, therefore, within a portion of Mr. Bateman's area that your observations would apply?—Yes, certainly.

2094. (*Chairman.*) Do you know if there is any considerable portion of that area under high cultivation?—No, not at all a considerable portion. I should say that certainly one-tenth of it is not cultivated at all. Nine parts out of ten are mountain sheep walks.

2095. (*Mr. Prestwich.*) Is that cultivation extending at all on the sides of the valleys?—Not recently, because the sheep have been increasing in value.

2096. (*Chairman.*) The water would be an unexpected mine of wealth to the landed proprietors?—Yes, that is the way in which I put it.

The witness withdrew.

Adjourned to to-morrow at 11 o'clock.

Thursday, 21st March 1867.

PRESENT:

SIR JOHN THWAITES IN THE CHAIR.

Colonel HARNESS.
Alderman Sir BENJAMIN PHILLIPS.
THOMAS ELLIOT HARRISON, Esq.
JOSEPH PRESTWICH, Esq.

T. Duncan, Esq.
1 March 1867.

THOMAS DUNCAN, Esq., examined.

2097. (*Chairman.*) Are you a civil engineer?—I am.

2098. Are you engineer to the Liverpool Waterworks?—I am.

2099. Are those works under the municipal authority of Liverpool?—They are.

2100. Have you been long engineer to that corporation?—I have been over 23 years engaged in the Liverpool Waterworks, and for the last 16 years I have had the entire charge of the home works, and more recently I have been engineer in chief of the whole of the works.

2101. You are supplied at present from what district?—We are supplied from two sources, one a catchment, and the other from wells; we draw a considerable quantity of water from the wells out of the new red sandstone in the neighbourhood of Liverpool, and the other portion from Rivington. You will observe on the map the district of Rivington, and the black dotted line shows the pipe line down to Liverpool.

2102. Is that the main source of supply?—Yes, that is the main source of supply.

2103. What is that district coloured higher up?—That is the Hodder district. In the investigation which I was requested to make for extending the supplies to Liverpool I had occasion to examine this district.

2104. That forms no part of your present source of supply?—No.

2105. Is that which you have pointed to as the present source of supply found equal to the requirements of Liverpool?—No, it is very deficient indeed.

2106. What was the anticipated quantity of water which you expected from that area?—16,000,000 gallons a day for the use of Liverpool was Mr. Hawksley's calculation, based upon a mean rainfall of 48 inches, but we have fallen very much below that.

2107. Do you remember what Mr. Hawksley's calculations were as to the quantity of water that would run off after allowing for absorption and

evaporation ?—75 per cent. ; he took off a quarter, and then he allowed one-third of the remainder for compensation to millowners and others having water rights on the streams which we take.

2108. Still he calculates so much water ?—Yes.

2109. 36 inches out of the 48 would be available either for the supply of Liverpool or the compensation of rivers ?—Yes, and he gave off one-third.

2110. What has been your experience with regard to that area as to the rainfall for the supply of Liverpool ?—If you will allow me I will hand to the Commission copies of my reports, the one is a report referring to the catchment scheme, and the other is a report referring to the present source of supply and also to another project which I brought before the Corporation of Liverpool. (*The witness handed in the same.*)

2111. What is the area of your present gathering ground ?—10,000 acres.

2112. Mr. Hawksley calculated that out of the mean average of 48 inches he would have available either for the supply of Liverpool or compensating the rivers 36 inches ; what has been the result of the practical working ?—It has fallen very much below that ; the mean rainfall of the district itself has been very much below that. If you will have the kindness to turn to Appendix C. in the report of July 1866 you will find it stated that the mean of 17 years was 45·70.

2113. That is 2¼ inches less than Mr. Hawksley calculated ?—It is, but as you will observe the minimum is very much below that, and it is in the years of minimum rainfall where the difficulty is experienced.

2114. You therefore have now a mean fall of 45·70 ; do you find that you realize 75 per cent. of 45·70 ?—If you will turn to Table D. you will find another table which will give you the result.

2115. That table shows that in 1865 it was 67·12 per cent. of the rainfall ?—Yes, and in 1862 it was 82.63.

2116. That gives a mean of 75·61 ?—Yes.

2117. So that that would seem to confirm Mr. Hawksley's view ?—Mr. Hawksley's calculations, taking the rainfall as he was then from the best information which he could obtain able to determine, were right, but unfortunately it has been found that we have had some years when we have not had anything like the quantity off the ground that he estimated as you will observe.

2118. We want first to ascertain whether the general principle laid down by Mr. Hawksley has been realized in practice ; it is another question as to whether the minimum fall would be equal to your requirements. Can you point to any year or years in which the rainfall has been very much less, and what has been the inconvenience which you have experienced ?—In the year 1865 we had 34·80 inches of rainfall. From my observations during that year, the per-centage of rain impounded was 67·12 per cent, which was very much below the 75·61, and that from a much smaller rainfall, of course, gave a very much smaller quantity of water for the ground. During that year the average daily quantity impounded, as you will find in the fourth column from the left hand of the table, was 14,476,865 gallons per day. We suffered great privations in Liverpool during that year, inasmuch as while we were only receiving for Liverpool from the catchment 6,176,865 gallons, after having given off 8,300,000 gallons as compensation which we were obliged to do by the Act, we gave away as compensation a larger quantity by about 2,000,000 gallons than we received for ourselves. (*The witness handed in a diagram. See Appendix R.*)

2119. You were under statutory obligation to compensate the rivers to that amount ?—Yes, we were.

2120. If I understand rightly, in the year 1865 you received eight per cent. less from that gathering area than the amount calculated by Mr. Hawksley?—We did.

2121. Was that eight per cent. due to the diminished rainfall or was it due partly to the absorption and evaporation arising from the condition of the ground ? —Both causes must be taken in connexion with each other. During the year when you have a minimum rainfall the showers come very lightly, and although they may count in a gauge, they do not in the streams. The rain is evaporated in many instances as fast as it falls, it neither reaches the ground to sink into it to come out in springs below, nor does it come off the ground into the rivers ; it is not in sufficient quantity. From my observations slight showers do very little good indeed to the impounding of water. It will vary very much as the nature of the surface of the ground varies. If you have a very steep descent and a very retentive subsoil or rocks that are not easily permeated by water, you will get a larger quantity down, but if you have a flattish country and an absorbent rocky or gravelly soil, you will get a smaller quantity. Hence, in a year when you have a succession of light rains you do not receive the benefit, and that accounts in my mind for the discrepancy in the per-centages which have been obtained.

2122. Is not that to be accounted for by the condition of the ground, its heat, its dryness, and its power to absorb as well as by the evaporation ?—Certainly.

2123. (*Mr. Harrison.*) Looking first at your second column and then at your sixth column, you do not appear in any one year to have had a loss of as much as 12 inches. That is to say, in 1861 the rainfall was 46·38 inches, and then, taking the proportion which is what you realize at 35·77, that is slightly under 11 inches. If you take the next year as 48·51 against 40·08 that is a loss of 8 inches. In the next year it is 51·01 against 40·72, that is under 11 inches again. In the next year it is 39·035 against 27·85, which is the only year in which the loss is over 11 inches ; and in the next year it is 34·80 against 23·35, making a loss of 11½ inches. Therefore, whatever your rainfall be, whether it be large or small, the actual loss would seem to be very nearly the same ?—The amount of evaporation and absorption does not vary much.

2124. (*Colonel Harness.*) Which would your experience lead you to prefer, a proportion of rainfall to be deducted or a definite quantity to be deducted ?—I should prefer a definite quantity if I could so arrange it and I would do it in this way. In a given area where the waters were collected into one reservoir, I would give out as compensation a proportion equal to what I drew off for use elsewhere. But to say that you will fix a given quantity upon a mean of years I think is fallacious, and it is shown to be so from my experience at all events. For as I pointed out just now, when we were giving off what was a fair quantity calculated upon a third of the water which found its way into the reservoirs in the mean of years, we were only receiving for Liverpool 6,000,000 gallons, while we were giving off 8,000,000.

2125. My question alluded to the estimated loss by evaporation and not to compensation to the streams. Which would you prefer in making a fresh estimate, to estimate the loss by evaporation on a proportion of the rainfall or on a definite quantity ?—You may take the proportion of the rainfall as very nearly correct, taking it in connexion with the physical character of the district over which you collect your water, it is then a matter of opinion which mode you would adopt. If you take the same basis in each case it is of very little consequence how you give it off, if I understand your question correctly.

2126. It seemed a question whether the quantity of between 11 and 12 inches lost by evaporation was not nearly constant, although the quantity of rainfall varied. Would you in future, in making such estimates, prefer to take a definite quantity of say 11 or 12 inches ?—Yes, I would be inclined to do so if it were based upon observations extending over a sufficient number of years.

2127. (*Mr. Harrison.*) Let me call your attention to Table D. again. It appears that Mr. Hawksley originally calculated upon a mean rainfall of 48 inches. In 1862 you appear to have had for the consumption of mills 8,300,000 gallons, and left for the town or run to waste 16,544,000 gallons ?—That is so.

2128. That is really exactly corresponding in that case with Mr. Hawksley's calculation of one-third for the mills and two-thirds available for the town ?—Yes.

T. Duncan, Esq.

21 March 1867.

2129. But when you come down in 1865 to 34 inches the 8,300,000 gallons is still a constant quantity and reduces what you have for your town supply to a less amount than you really have to supply the mills?—That is so.

2130. Therefore it is hardly perhaps correct in taking this as a basis for calculation that you should take one-third for consumption in order to make the calculation valid, it would seem that you ought to assume a fixed quantity for the mills?—Yes, it ought to be upon the minimum rainfall. I think that calculations for the supply of towns should be upon minimums and not means, and I think there is a note in my report to that effect. That is the conclusion to which I have arrived by observation.

2131. In point of fact, unless you take the minimum or unless your storage will carry you over 12 or 18 months, you are quite sure to be deficient?—Yes; in wet weather the millers get the advantage, and in dry weather they have a very much larger quantity than they would have received had they been depending entirely upon the natural flow of the rivers.

2132. (*Chairman.*) Therefore your principle of compensation has rather given a regularity of power to the millowners than that which they previously enjoyed, that is to say, in the case of drought, there would be no such thing as drought in the river under the present arrangement?—No; the river would be kept, exceping in time of floods when you could not retain the waters, at one equal flow.

2133. A flood itself would be no advantage to the millowner except as giving him the power of impounding the flood water to the extent of his capacity?—To a miller who had adjusted his machinery to the ordinary flow of the river, it would be very little or no advantage, but it would be a great advantage to the river to have a flood now and then.

2134. But taking the millowners, and looking simply to their interests, are you of opinion, having regard to your experience, that they are under as favourable conditions now as they were before this arrangement was come to?—Yes, far better. They can now depend upon what they have to get, whereas formerly they trusted entirely to floods.

2135. Before this arrangement was come to in very droughty weather the river must have been in a condition that they could not work their mills?—Yes.

2136. Whereas now they have a constant supply?—Yes. Taking our own case, the Leeds and Liverpool canal, which receives water from us, given out at one point, about 3,000,000 gallons of water a day which flows constantly. I have seen the stream before the works were constructed when there was not more than one-third part of that quantity flowing down, now they have it constantly, and they have the first draw.

2137. I understand from your answer that the original calculation made by Mr. Hawksley has, in point of fact, been confirmed, and you only differ from him in accepting the minimum fall instead of the mean?—Yes.

2138. What is the general character of the area from which you take your supply; is it cultivated at all?—Partly; I should say that five sixths of the land is moor and sheep pasture land covered with heath, and some portions of it mossy, the geological formation being millstone grit chiefly.

2139. Is any part of it under cultivation?—A very small portion of it is ever ploughed; I should say not one-fiftieth.

2140. Can you trace any pollution of the water to that cause?—No, I think not; I think it is scarcely appreciable, the ratio is so small in comparison.

2141. (*Sir B. Phillips.*) What is the quality of the water?—It is very good; it is under three degrees in hardness. I can hand in to the Commission, if they desire it, a copy of Professor Way's analysis of the reservoir water, and samples of the river waters.

2142. (*Chairman.*) I understand that the question of an increased supply to Liverpool has been under the consideration of the corporation?—It has.

2143. And you have been directed, have you not, to report to the corporation upon that subject?—I have.

2144. And are the reports which you have handed in founded upon that investigation?—Yes, those are the reports which I have handed in.

2145. To what source have you directed your attention for an increased supply?—I have looked first of all to the source of the Hodder, and I have considered the river Ribble and the lakes; first of all there is Windermere Lake.

2146. There is a part of the coloured watershed, amounting to 43,315 acres above your present supply, intervening between Preston and Lancaster, and the east; what does that refer to?—That is simply the drainage area of the river Hodder down to its junction with the Ribble—43,315 acres.

2147. That 43,315 acres is represented by that portion coloured yellow on the map?—Yes.

2148. Then there are two other watersheds?—Yes, the one 5,000 and the other 13,000 acres; those are the portions which I assume we would be able to impound.

2149. Therefore it would be a little over 60,000 acres?—Yes, I think so.

2150. What do you calculate would be the yield of that district?—Very much like the Liverpool district.

2151. It is six times the area, is it not?—Yes, but it would be in the same ratio; I take the rainfall of this district as very much like that which we find at Rivington.

2152. Is the geological formation much the same?—The lower part of the valley is chiefly lime; the upper portions are partly millstone grit and partly lime.

2153. Then you would have hard water?—Yes, unless by going well up, and that is the reason why I have assumed that the upper waters of the Hodder should be taken; I had two objects in view, the one to get sufficient altitude and the other to get better water, as there would be very little limestone area in it.

2154. I presume that you could convey the water that you have occasion for from this district to Liverpool?—I could.

2155. What head does that give you?—It is an an average fall of 3 feet per mile as far as the Rivington works.

2156. Have you any pumping?—There would be no pumping there.

2157. At what height are you above high water at the Liverpool Waterworks?—I would explain that the project for this portion was examined with the view to deliver the water into the Anglezark reservoir, and so send it down by our system of pipes to Liverpool; I was required to consider this because it had been thought by several parties that this was a favourable place to go to to look for water; and it was suggested that it could be taken into our Liverpool system and made a part of it.

2158. If I rightly understand the colouring of this map you bring your water from that area, and utilize your present tunnel or aqueduct?—The suggestion was that we should utilize the present works.

2159. Is that aqueduct of sufficient capacity for the increased supply?—No, certainly not.

2160. How do you propose to deal with it?—A new line of pipes would require to be laid.

2161. What size are your present pipes?—Our present pipes are 44 inches in diameter; in point of fact it would be wholly a new work.

2162. How many have you?—Only one up to Prescot, which is eight miles from the Exchange, and from Prescot into Old Swan, where we divide the water, which is $3\frac{1}{2}$ miles from the exchange, I have two lines of pipes, one 44 inches and another 36; the 36-inch pipe has only been in use for a year and a half.

2163. Then, in fact, you would supplement your pipe arrangements?—Yes.

2164. They are all iron pipes I suppose?—Yes,

excepting about three quarters of a mile of tunnel coming through the summit near Rivington.

2165. Then the water from your new source of supply would also be conveyed in iron pipes?—Yes, excepting the upper portion for some distance along the line which you see marked red from the proposed watershed coloured green and pink; a considerable portion of that 10 miles might be in tunnel or culvert formed along the contours. Then passing the valley of the Ribble we should have to use pipes, and we should use pipes beyond that for the greatest portion of the way.

2166. Why have you elected to use pipes instead of an open culvert or tunnel?—In passing through a valley, unless you can get ground suitable, you cannot work under a pressure in the open, whereas you can do so with pipes.

2167. You have a great number of syphons, I suppose?—Yes.

2168. (*Mr. Harrison.*) Do you filter the water at all?—Yes, we filter all our Rivington water.

2169. (*Chairman.*) Is that found necessary?—Yes, absolutely necessary.

2170. I presume that that is done in order to free it from anything held in mechanical suspension?—Yes, all that is held in suspension is taken out by the filter; we cannot get rid of the colour, though we take out a portion of it.

2171. Have you any peat in your district?—Referring to the suggested Hodder district, there is a little at the very top of the hills, but the higher we go up this stream we find the water becoming more brown until it is mixed with the whiter waters which come off the limestone below. The upper waters come off the millstone grit. The water of the greatest altitude is the softest water, although it is more highly coloured than the lower waters.

2172. Have you any peat in the area of your present supply?—We have.

2173. How do you get rid of the discolouration?—By filtration.

2174. Will filtration accomplish it?—To some extent, we use filtration alone. We use nothing else but an ordinary sand and gravel filter. We find there is as little colour left in it as there is in nearly all mountain waters, and probably a little more at one time than another.

2175. What was the character of the water supplied to Liverpool prior to the present supply?—It was derived from wells sunk in the red sandstone.

2176. Do you remember the properties of that water; was it hard?—Generally hard. One or two wells were better than the rest. With regard to the Green Lane well for instance, which is the best of all the waters, when first we got water there, we had an analysis made, and it was about 4½ degrees of hardness; it is now about 7. I have not had it analysed very recently; about 7 is the correct degree. The other wells in the town were very much harder. I can hand in a table of the analysis of those waters if the Commission wish it.

2177. (*Sir. B. Phillips.*) Do you continue to use the waters from those sources?—We are using the water from Green Lane, Windsor, Dudlow Lane, Bootle, and Water Street.

2178. Are those all the sources from whence your water was supplied before the construction of the Rivington Pike scheme?—No, we had several other wells; we had Hotham Street, and the Bush and the Soho Street stations.

2179. What quantity of water per day used you to receive from those various wells?—35,000,000 gallons per week. From the old sources the greatest quantity we ever raised from all the wells together was somewhere about 42,000,000 to 43,000,000 gallons per week.

2180. Have you discontinued the use of a certain portion of those wells?—Yes.

2181. Do you know how much water you receive from those portions which you continue?—Yes.

2182. How much do you receive from those sources now?—Generally about 38,000,000 or 39,000,000 gallons; it varies occasionally.

2183. (*Chairman.*) Your object in seeking this fresh source of supply or the result of it would probably be to discontinue the supply from those wells?—Yes, no doubt.

2184. Then the water from some of those wells was of very much greater hardness than the water from one or two wells which you say was something like seven degrees of hardness?—It varied considerably.

2185. Have you observed in Liverpool, or has your medical officer reported to the Corporation, the effect of this soft water which you have been using for some years past as compared with the use of hard water previously?—I had occasion to receive a communication from our medical officer during the autumn of last year, when I was requested, if possible, to give a larger quantity of the hard water into a district of the town than I was giving. No doubt he had good reasons for asking me to do so. I did not quite understand him; I had always been given to understand that the softer and purer the water the better.

2186. Did he ask you specially to supply the hard water, or did he ask you for an additional supply of water, knowing you were limited elsewhere?—This requires a little explanation. We have several reservoirs at home in the neighbourhood of Liverpool into which we receive the water from Rivington and also the pumped-up water from the wells in the district, there was very great difficulty, in consequence of the structure of our mains, in getting such a quantity of well water or Rivington water, as the case might be into one reservoir as there was in another; and what the medical officer wanted, after having made an examination of some districts of the town, was to equalize the quality of the waters, and that equalization was to be brought about by getting a larger quantity of well water into a district which was getting a softer water than the others. I made some arrangements; they complied with his request, so that now the quality of the waters throughout the whole district is very nearly alike.

2187. Did he ask for that water on account of its hardness?—I believe it was on account of its hardness. If you will permit me I will hand in the letter which the medical officer sent to me. (*The witness handed in the following letter*):

"Public Offices, 2 Cornwallis Street,
"Medical Officer of Health's Department,
"Dear Sir, Liverpool, June 16, 1866.

"In obedience to a resolution of the Mortality Sub-committee, I herewith forward to you a copy of Dr. Sheridan Muspratt's analysis of three samples of the service waters of Liverpool taken from the main pipes situated in the northern, southern, and central districts of the town.

"There are, in the results of this analysis, some points of hygienic interest, which, having attracted the attention of the Committee, I beg also to bring before your notice. The first is the difference in the quality and in the saline or foreign constituents of these waters. This is as great as what will generally be found to exist between those of towns placed several miles apart, and in geological formations of very dissimilar character. Now, though variety in food is a cardinal axiom of dietetics, yet, in the case of drinking water, it is found that the slightest change from what the stomach has been accustomed will in delicate persons occasion dyspepsia and visceral derangement. Indeed, I can readily conceive, that a weakly person used to the hard water of Toxteth Park will be very disagreeably inconvenienced by drinking the soft water of Hornby Street, and *vice versâ*. It is desirable, therefore, on general health principles, that, if possible, the water supplied to the whole borough should be homogeneous and the same in quality at all times and all seasons.

"The next point to which the Committee's attention was called was the amount of the nitrates and of organic matter in the several waters. It is presumed that none of the samples were either pure "well water" or unmixed Rivington water, but that the latter predominated in the Hornby Street sample, the former in that of Mann Street. Now, taking the amount of nitrogen in the 0·6361 of a grain of the nitrate magnesia to represent 0·2 of organic matter, we have 0·900 or nearly one grain of organic matter in the water of Hornby Street. This is pretty much what was found by

T. Duncan, Esq.

1 March 1867.

Dr. Lyon Playfair in 1847 to exist in the stream below Anderton Ford, and, therefore, it is so far satisfactory to know that the waters of the lake have not been materially, if at all, deteriorated by being impounded from a large area of ground.

"You will probably remember the purport of Dr. Fairplay's conclusion which, to use his own words, was: "Organic matter is never to be desired in water, but in the "present case (Rivington streams) it is present in very "small proportions, so small as to be wholly innocuous." I do not venture to differ in opinion with this high authority, but still I think that if by a more liberal mixture of well water you could not only bring the Hornby Street water to be on a par with that of Abercromby Square, but also lessen proportionally the quantity of its organic matter, it would be desirable to do so.

"In the case of the Mann Street supply, a skilful admixture of the Rivington water would lessen the amount of saline ingredients and make it, if not more wholesome, at least more useful in household economy. At the same time it must be admitted in the favour of our present system that 19 grains to the gallon is less than what used to be found in the water supplied by the Bootle Company or the Liverpool and Harrington Company.

"In conclusion, I think I give expression to the opinion of the Mortality Committee by stating:

"1stly, That it is desirable, if possible, that the water supplied to the borough should be homogeneous, and that to secure this being the case at all times and all seasons an analysis of the waters supplied to the several districts should be published at stated periods.

"2ndly, That in attaining this homogeneity in quality an endeavour should be made to bring all the water of the borough to the purity of that now supplied in Abercromby Square.

"I remain, &c.

"Thomas Duncan, Esq., W. TRENCH."
Water Engineer."

2188. With regard to the change from one water to the other, have you any evidence to show that it has had a beneficial effect upon the human system?—I know that washerwomen and brewers grumble at the hardness of the water. I have frequent complaints of the water being very hard in the districts; for instance, at the very last committee that we had at Liverpool several complaints were made of the hardness of the water. We were getting from our new works a rather larger quantity of hard water than was liked for most purposes; although the well water is preferred for drinking, for all other purposes the softer water is preferred.

2189. Had you any report from your medical officer upon that subject?—I had no report from him.

2190. How long has the present system of supply been in operation; I mean other than from the wells?—The mixed water has been supplied to Liverpool a little over 10 years.

2191. Has the medical officer made any report during those 10 years with regard to the improved health of the town, and has he attributed it to the change of water?—He has made several reports, but I am not provided with them; he has made a number of reports upon the sanitary condition of Liverpool, but I do not remember them just now.

2192. Can you give this Commission some evidence as to the advantage of the soft water over the hard water for manufacturing and other purposes?—Brewers like the soft water better; they get a better extract, and can make a better beer, and distillers like to use it for breaking down spirits.

2193. Can the brewers make the light bitter beers from the water?—I do not know that Liverpool is very celebrated for its beers, but they like Rivington water much better than they do the well water.

2194. You mean for making porter?—No, they make a comparatively light beer; I have had many complaints of giving them hard water. When I have been obliged, from some cause which I could not prevent, to give them a larger quantity of hard water than they have been accustomed to, they have complained very bitterly.

2195. Do you find that they detect the presence of hard water without any notice being given to them?—Yes; this may be partly owing to treating the one water the same as they would the other without having been warned; a part is due to that, but the most part is due to the water itself.

2196. For general manufacturing purposes, such as dyeing and scouring, is soft water better?—There is no doubt about it that soft water is better.

2197. (*Sir B. Phillips.*) You have but very few manufacturing interests in Liverpool, I think?—We have a good deal, but not stuffs; we sell about 1,500,000 gallons per day for trade purposes in Liverpool; there are no dye-works, or only very small ones.

2198. I understand you to say that you derived from the well sources originally something like 35,000,000 gallons per week, gradually increasing up to 43,000,000?—Yes, that was the maximum.

2199. Certain portions of those wells you continue still for the supply of the town?—Yes, we do.

2200. Can you tell me up to your last year what quantity was drawn from the well sources?—We have it, for instance take November 1866, the quantity was 40,000,000; 39,000,000; 39,000,000; 39,000,000; 39,000,000; 40,000,000; 37,000,000; 35,000,000; 35,000,000; 40,000,000, and so on.

2201–2. So that you really retain as large a supply now from your old sources as you took from them before?—We do as a whole, but not from the particular sources. We abandoned in 1858 some of our wells, and we have increased the quantity since then from the others.

2203. How many wells have you altogether in number?—First of all we had the Bush, Soho, Water Street, Hotham Street, Windsor, Green Lane, and Bootle; we had seven wells.

2204. How many have you abandoned?—We have abandoned three—Soho, Hotham Street, and the Bush.

2205. Then you have increased your supply from the remaining four?—Yes; I am now getting from Bootle an increase of nearly 1,000,000 gallons per day. I am carrying out works there at this present time, and at Dudlow Lane, which is a new station, I am getting 400,000 gallons per day. During 1866, when we were short of water at Rivington, we pumped all that we could obtain from the wells.

2206. If I understand you correctly, you derive nearly as large a quantity from the four wells that you retain as you did when you had seven?—Yes, that is so.

2207. And you derive from the four wells that you retain as large a quantity now as you always did, even before the introduction of the new source of water supply?—Yes, about that.

2208. If I am correctly informed, the water from the wells is hard?—Comparatively hard.

2209. And the water that you derive from your new source is soft?—From Rivington it is.

2210. In what way do you supply the hard water to the different houses?—It is mixed in the reservoir and distributed along the pipes; we mix the one water with the other; there are certain reservoirs in the neighbourhood of Liverpool from which we distribute the water.

2211. What degree of hardness is the water when mixed?—I have here an analysis of samples of mixed water taken from three districts of the town at the time when it was considered desirable to have the water somewhat changed, and this is the analysis to which the medical officer refers:

"To Dr. Trench, Medical Officer of Health to the Borough of Liverpool.

"College of Chemistry,
"Liverpool, June 8th, 1866.

"SIR, Liverpool Service Waters.

"I BEG to hand you herein my analysis of the three samples of "Liverpool Service Waters" left with me for examination on the 23rd May last. The samples were labelled thus:

Sample:—"69, Mann Street."
"6, Hornby Street."
"Abercromby Square."

And represented as having been taken from the service-pipes of the places named.

"An inspection of the waters showed they were quite free from solid matters in suspension, and when viewed through a 10-inch column they presented a translucent and colourless appearance.

"A careful qualitative analysis of the waters severally indicated the presence of carbonate of lime and magnesia, sulphate of lime, chlorides of sodium and of magnesium, silicate of soda, carbonate of soda, *traces of nitric acid* in combination, organic matters, and small though very distinguishable traces of ammonia in each.

"The respective amounts of these several bodies were estimated with the greatest care and calculated to the imperial gallon. The table annexed contains the result thus obtained:

TOTAL AMOUNT of SALINE and other BODIES per Imperial Gallon in the Liverpool Service Water from:

	6 Hornby Street.	69 Mann Street.	Abercrombie Square.
Carbonate of Lime	0·5694 grains.	3·9050 grains.	1·8866 grains.
Carbonate of Magnesia	0·8953 „	3·0359 „	1·2386 „
Sulphate of Lime	3·8750 „	6·2676 „	2·4658 „
Chloride of Sodium	1·7886 „	4·2968 „	1·6010 „
Chloride of Magnesium	0·2865 „	0·3817 „	0·1404 „
Silicate of Soda	0·0211 „	0·0810 „	0·1011 „
Carbonate of Soda	trace.	0·0201 „	0·0250 „
Nitrate of Magnesia	0·6361 „	0·1641 „	0·0922 „
Organic matter and traces of Ammonia	0·7013 „	0·6538 „	0·6670 „
Total per gallon	8·7733 „	18·8060 „	8·2677 „

"The several samples mentioned have a persistent alkaline reaction, from the presence of carbonate and silicate of soda, in them. They have not the property *of dissolving metallic lead* so as to retain it in solution.

"(Signed) SHERIDAN MUSPRATT, M.D.,
"Professor of Chemistry."

2212. I think you stated that you have experienced some disappointment from the original calculations that were made as regards the quantities of supply from the new sources?—Yes, no doubt in the years of small rainfall we have.

2213. So much so that you have not had so large a supply as you contemplated?—That is so.

2214. But nothwithstanding that Mr. Hawksley's propositions with regard to the rainfall have proved to be pretty nearly correct according to that calculation?—That is so. The only error made I think was in taking a mean instead of a minimum.

2215. As engineer to the Liverpool corporation, you have been requested, have you not, to suggest a system by which you could increase the supply?—I have.

2216. In addition to the quantity which you have already, what quantity do you propose to supply?—I propose first of all to go to Bala Lake, to commence with such a quantity by laying down one main as would deliver 15,000,000 gallons a day.

2217. What is the distance from Bala Lake to Liverpool?—Close upon 70 miles along the pipe line.

2218. (*Chairman.*) Do you propose to abandon that area which you described a short time ago?—I never contemplated using it. I was directed to examine it and to report my opinion as to its capacity and the physical possibility of conveying the water to Liverpool or rather to our works at Rivington.

2219. Having examined and reported upon that, and also having examined the Bala Lake district, you preferred the latter?—Yes, I preferred the latter, certainly, to all other sources.

2220. (*Sir B. Phillips.*) You say that the distance is 70 miles, and you propose to recommend Liverpool to derive its water by certain means from a source 70 miles off?—Yes, I have recommended it in the report which I have had the honour of handing in to the Commission.

2221. What is the population of Liverpool?—Within our district of supply I compute that we have 600,000, about one-fiftieth part of the whole empire.

2222. What quantity of water per head per diem do you recommend?—In going for a new scheme I would make a large allowance; but I think nothing less than 30 gallons per head per diem is sufficient. With well constructed works, and with a well regulated supply, 30 gallons per head per diem should be enough.

2223. In any scheme which you might recommend for an increased supply of water to Liverpool, should you feel yourself justified in suggesting or recommending to the local authorities that they should under any circumstances abandon their means of local supply?—If we were to go to Bala, I would not have the slightest hesitation in recommending the corporation to suspend their pumping. I have no doubt that the district to which I have alluded in my report is sufficient to supply Liverpool for very many years to come without any assistance from the home sources.

2224. And you think it would be perfectly safe to discontinue the pumping?—I have no doubt in my own mind that we should be perfectly safe, because the district is so extensive that the quantity of water to be taken for the use of Liverpool from it can be extended as the requirements of Liverpool grow. The whole of this district is capable of yielding 100,000,000 gallons a day for our supply, at the same time giving a sufficient quantity of compensation water down the rivers for the use of those having rights in the water.

2225. (*Chairman.*) When you speak of 30 gallons per head per diem, is that an inclusive quantity, or is it exclusive of water for trade purposes?—For all purposes.

2226. In calculating for the commercial requirements of such a town as Liverpool, as well as the supply of the inhabitants for domestic and other purposes, is an average of 30 gallons per head per diem a sufficient supply in your judgment?—Very much would depend upon the character of the town, whether it is a manufacturing town or not; but speaking of Liverpool, I think that if we had 30 gallons per head per diem, with the power of extending the supply as the town grew, we should have about a fair and sufficient quantity. But I do know this, that the uses of water are being increased in all directions, and that the tendency is to use a larger quantity of water day by day. Such are the household arrangements now that we require a larger quantity of water, from the cleanlier habits of the people and other causes.

2227. What area have you directed your attention to in the Bala Lake district?—The basin of the Dee and also of the Elwy, and the Aled being a tributary of the Elwy.

2228. What acreage do you think would be necessary for the supply of Liverpool in addition to your present source of supply from the wells?—I would take the whole of this district, that is to say, the 35,000 acres which you will see coloured blue, the 14,000 acres, and the 11,000 acres.

2229. I presume that the area of Bala Lake and the gathering ground generally would be sufficient for the supply of Liverpool independently of your present source?—Quite so for a long time.

2230. And the supply would be capable of expansion equal to the growing population of the town?—Yes, that is one of the merits of going into a district where you can extend your supply.

2231. What is the difference in mileage between the

T. Duncan, Esq.

21 March 1867.

district which you have surveyed on the north and the Bala Lake district?—Taking into consideration that after we had got the water down to the Rivington works from the Hodder we should be obliged to continue the works on to Liverpool, there may be about 10 miles difference.

2232. And the difference of cost of course would be in that proportion?—Yes. The Hodder district is wanting in one of the essentials to any scheme; it is not capable of being extended to such a length as the Bala district. The Bala district contains all the elements of a great and good supply, that is to say, the water is pure, it is abundant, and there is plenty of space to gather more.

2233. You propose, do you not, to take your supply direct from Bala Lake and to utilize the lake as a natural reservoir?—Yes, and the plan of making it a reservoir has many advantages.

2234. Would you increase the quantity by tapping?—Yes, by raising it up so as to keep the outflow level up to high-water mark of the present floods. The highest flood mark would be the sill of the by-wash.

2235. What is that beyond the ordinary surface level?—It is about 5 feet, and I should draw off so much below.

2236. Would that flood a large acreage?—No, it would flood nothing more than what is flooded now at high water.

2237. Would not it involve compensation?—It would avoid all compensation so far as flooding new land is concerned. That was one of the objects which I had in view.

2238. Is that quite so; you may have an occasional flood in the winter, or say floods in the year, that is one condition of things, whereas you propose to flood the land and to take possession of it?—No, not to flood the land.

2239. If you raise permanently the surface level of the lake and flood it to the extent of the highest flood in the winter, you are permanently taking possession of so much area, are you not?—I quite understand your question. I would not flood any additional land, because the bye-wash would be of such a width and such a height as would prevent the water rising as it does now by being throttled at the outlet of the lake. By giving it an expanded bye-wash and keeping the head of the water low I should have the means at command of keeping the water down and so preventing any flooding of the land which does not now take place.

2240. My first question is this; do you propose to raise the surface level of that lake and to increase its storing capacity, and your answer, if I rightly understand it, is that you do propose to raise it 5 feet?—Yes.

2241. And I understand that that is to be a permanent raising?—Yes.

2242. Then I want to know what increased acreage that would flood?—I have not ascertained the breadth. The margin of the lake on one side is precipitous; upon the right bank of the lake there is a railway which has been recently constructed and which runs along the very margin of the lake, so that a portion of the right bank as well as the left bank is also tolerably precipitous, and the quantity of additional land that would be flooded, that is to say, the present beach which would be permanently flooded, would not be a very large quantity, but I have not ascertained precisely what it would be.

2243. You would have to take the rail higher up otherwise you would flood the rail, would you not?—No, we should not flood the rail; the rail is about 8 feet above the margin of the lake.

2244. (*Mr. Harrison.*) Is not this what you propose to do, to make your bank sufficiently high to retain the waters at the present highest flood line?—Yes.

2245. And to provide such an extensive bye-wash as would keep the floods that would pass off from rising so high as to flood the lands?—Yes, that is my view.

2246. (*Chairman.*) What quantity do you think this area which you now propose to utilize would yield?—A large quantity. I calculate that the lake would be able to give us 30,000,000 gallons a day before we require to construct any large additional works for compensation water.

2247. Do you know the rainfall of that district?—That is a question which is not very well determined. I have looked at all the available gauges, but in order to be safe I have taken the quantity at what I consider to be the minimum; I have taken it at 36 inches; I have taken off a fourth from that for loss, and then I have allowed of the remainder one-third to go for compensation and the other two-thirds to be taken to Liverpool.

2248. I understand that you have taken off 9 inches, and your evidence is, that there is a loss of from 11 to 12 inches?—That is in the other district. In the Bala district I am inclined to think that the loss would be much less. The rocks are less absorbent; they are of a hard, slatey character; the slopes of the hills are steeper and the waters would come down more suddenly, and would reach the valley in a larger volume in proportion to the rainfall than the water at Rivington does.

2249. At all events the area is so large that it is quite capable of yielding the quantity which you assume?—Yes.

2250. Do you propose to take it by means of iron pipes?—First of all by a culvert which would carry 60,000,000 gallons a day. I propose to make that a permanent work down to the reservoir which you will observe marked on the map near Llangollen.

2251. The population of Liverpool, I think you state, is 600,000?—Yes.

2252. (*Mr. Harrison.*) Are there 600,000 now?—Yes, within the district of the supply which extends over 60 square miles.

2253. (*Chairman.*) Allowing 30 gallons per day what would that make your present supply?—18,000,000 gallons.

2254. And you would give to the culvert, or whatever you construct, a carrying capacity of 60,000,000 gallons a day?—Yes. If you will follow the red line from the bottom of the lake the ground is very favourable for the formation of such a work till we come down close to Llangollen. Between Llantisilio and Llangollen I propose to cross the Dee by a pipe by a special bridge constructed for the purpose.

2255. Do you cross there above the bridge?—Yes, above Llangollen. That would be upon the left bank of the Dee. Then attaining an altitute on the other side I continue the culvert on to the little square mark which you see upon the map. There I propose to construct a reservoir and make straining beds, and from thence by the red line I would go down and cross the Dee again near Holt, then across the Chester and Crewe line of railway, near to Tarporley, then through the Forest of Delamere skirting the high land, and at two of the most convenient points that could be found along the line I propose to construct certain relieving reservoirs; thence I should take it down across the Mersey by a special bridge over the river above Runcorn, and then on to Woolton.

2256. Is there any navigation above that point?—Yes; the bridge would have to be sufficiently high, just as the railway bridge which is now constructed there is sufficiently high, to admit of the craft which go up the river to pass through it. Then I go on to Woolton Hill, which is high land, in the neighbourhood of Liverpool; and from thence I propose to make connexions to the various reservoirs in the neighbourhood of the town.

2257. (*Colonel Harness.*) To what depth do you propose to draw the water in Bala Lake?—I have suggested 2 feet below the bridge at the present time.

2258. What would be the depth below the level of the lake?—It would altogether give me a power over the lake of from 6 to 7 feet.

2259. What capacity of storage do you calculate upon?—With the water which would flow into the lake, taking 20,000,000 gallons a day as the quantity to be supplied to Liverpool, it would be about 190

days. Then the other part of the project is this: from the little square dot which you see in the neighbourhood of Llangollen I would for the present time content myself with one pipe to deliver 15,000,000 a day, taking land of sufficient width, and making the permanent works, the bridges, and other appliances, sufficient for the addition of other pipes as they might be required.

2260. (*Chairman.*) Do you propose to have pipes all the way?—There is a small portion in the neighbourhood of Broxton, and a small portion near Frodsham that will be open, but I have calculated for pipes all the way from the reservoir upon the shoulder of the hill near Llangollen.

2261. How many pipes would you have?—In the meantime, until the supply is required to be greatly extended, I would have only one which would be sufficient to supply 15,000,000 gallons a day, and I would add pipe after pipe as necessity arose.

2262. What size would the pipe be?—A 44-inch pipe. I have taken the same data that we have in the Liverpool works.

2263. Do you propose to use a wrought-iron pipe?—In the valleys where the pressure would be greatest, I think it is quite possible to obtain steel pipes which would be much lighter, and I have been in communication with several manufacturers of steel in the country, and they tell me that they think that there is no great difficulty in obtaining steel pipes. Chemists tell me that steel pipes are less subject to corrosion than iron pipes, so that if we could obtain steel pipes they would be very little more expensive than the others. Wrought-iron pipes are more secure than cast-iron pipes, but I have calculated for cast iron.

2264. Your other system of supply has been in operation for 10 years, has it not?—Yes.

2265. What has been the effect of the soft water upon the iron pipes?—To produce an infinite number of small tubercles; those have grown up, and they project, in many instances, for about three-quarters of an inch, reducing the diameter of the pipe, between point and point, by $1\frac{1}{2}$ inch.

2266. And thereby, I presume, increasing the friction?—Yes; they form an infinite number of little eddies, and it is not only the space that they occupy in the pipe, but from my own observation I believe the effects extend much farther into the interior of the pipe and disturb the current; but comparing a pipe of $1\frac{1}{2}$ inch less diameter with the present pipe, I know that the pipe of $1\frac{1}{2}$ inch less diameter would conduct from Rivington to Liverpool a larger quantity of water than the 44-inch pipes do with those little tubercles.

2267. (*Col. Harness.*) Have you formed any calculation of the present discharge of those pipes?—They have fallen off very nearly 25 per cent., part of that I attribute, however, to their passing over some coal-fields where accidental depressions have taken place, and I have it under contemplation now to put in a number of small air cocks wherever we have those depressions, so as to take off the air, for I think the pipes have become partly choked, and will not run full.

2268. Have you got an arrangement for relieving those summits?—Yes; we have for the summits which existed originally, but accidental summits have been created, which we have not been able to overtake.

2269. (*Chairman.*) I suppose that apart from those depressions your pipes are always charged?—Yes, always charged, and running full under pressure.

2270. And yet, notwithstanding that, they are in the condition you have described?—Yes, that I find to be so when we have a fractured pipe and take it out.

2271. Where there has been no depression you do not attribute that condition of the pipe to the depression that might arise from the land sinking, and allowing the air to be in the pipe, but it is general throughout the pipe?—I am speaking now of the present state of the pipes.

2272. I refer to case of pipes that are level laid as they were originally, and under constant pressure, yet when they have been taken out for the purpose of examination and repair you have found them in the condition you have described?—Quite so, they are all alike in that respect.

2273. (*Mr. Prestwich.*) Have you had to replace any pipes in consequence of this deposition or incrustation?—No, we have had to replace fractured pipes occasionally, and in doing so I have discovered the condition of the pipes.

2274. (*Col. Harness.*) In the town delivery you would get some means of actually measuring the effect, would you not, because you have not had those sinkings there?—We have had no depressions in the town certainly, but the draught varies so in the town that I have never taken any means of ascertaining the difference of delivery in the pipes at different times, but I have no doubt of what takes place.

2275. That would admit, would it not, of a nice experiment?—No doubt. I will state to the Commissioners what I have done in the town of Chorley where the water has been laid on for 16 years. The qualities of the waters of Rivington and Chorley are very much alike, in fact they come from similar districts, and at Chorley we have an application at this moment to take up and relay a number of pipes in the town, because they have become choked up in consequence of corrosion taking place of the same character as I have now described. Some five years ago we had occasion to lift one of the small pipes which extended along the ridge of a hill where there was not much draught of water, and when taken out one could scarcely see through the pipe, it had become so incrusted.

2276. What was the diameter of that pipe?—It was only a 3-inch pipe. I have taken those pipes out and put down larger ones.

2277. (*Chairman.*) That projection which you have described to us is really from the substance of the pipe, is it not, and not a deposit?—Any matters that may be in suspension will adhere to the oxigenation of the pipe, and the little particles that may be in the interior of the pipe form a nucleus around which they gather.

2278. Have you taken any precaution against that by using the patent coating process?—I coat all the pipes that I lay down now by Dr. Angus Smith's process.

2279. What has been your experience of it?—I had occasion to cut out a pipe not more than three months ago which had been down for eight years, and I found the coating upon it not quite perfect, but in a great measure so. I consider it a very great advantage to coat all the pipes with that process.

2280. (*Mr. Harrison*) Were your pipes originally coated from Rivington Pike?—They were not.

2281. (*Chairman.*) In any pipes that you lay down now you adopt that or some other system of coating?—I adopt that system; I do not know of a better; I believe it to be the best at present known.

2282. The iron, I believe, is subjected to great heat and then put into the coating composition?—They have an apparatus at various foundries where they cast pipes. They warm the pipes in a species of oven, and they have a large tank in which this molten composition is kept; they dip them in, a number together when they are small, and fewer if they are large, or probably one if it is a very large pipe; they then take the pipe out and roll it away and allow the coating to dry, and it forms a perfect glaze upon it.

2283. What has been the external condition of your pipes that have been covered for a number of years?—A good deal depends upon the quality of the soil, but there is very little change upon them in general.

2284. (*Mr. Prestwich.*) Is there any difference in the condition of the pipes between Rivington and the reservoir at Liverpool, where you mix the water, and that of the pipes between the reservoir of mixed water and the town?—I cannot say there is. There is a tendency to the same kind of state in the pipes in the town that there is in the larger pipes bringing the water from Rivington.

2285. At what height do you deliver the water at Woolton Hill?—250 feet.

T. Duncan, Esq.

21 March 1867.

2286. What is the height of the starting point at Bala Lake?—530 feet I think is the water level.

2287. Do you base your estimated quantities entirely upon the assumed rainfall which you have just named or upon any gauging of the water?—Upon the assumed rainfall which I have taken and supposed to be the minimum.

2288. What is the nearest rain gauge in the Bala district?—There is a rain gauge kept at Bala at which I could learn nothing when I was there myself, but from Mr. Bateman's pamphlet I have looked at the matter, disregarding all those gauges, and taking what my own experience led me to; comparing that district with others, I have assumed a minimum rainfall of 36 inches, which I believe is lower than it really is, and which will make me quite safe.

2289. But you have no knowledge of what has been the maximum rainfall in a term of years at that spot?—I found nothing less than that in looking over the gauges of that district which are at all approaching to the same altitude.

2290. Do you know what the maximum rainfall of that district has been?—Over 70 inches; in one place I saw that the rain gauges had indicated over 100 inches.

2291. Notwithstanding the water is so pure, you think it necessary to filter it before delivering it to Liverpool?—I would pass it through a series of strainers; my object in taking the water at the lake was to avoid the turbid waters which occasionally come down the Dee. On my first visit to the Dee it happened to be after a rainy day, and the water was altogether unfit to take out of the Dee to use for the supply of a town. On the second day, when it did not rain at Llangollen, when I got to Corwen I found the river swollen and I met the flood coming down; there had been a very heavy thunder shower and the water was quite turbid; that confirmed me in my previous opinion that the lake was the proper place to go to.

2292. What quantity of organic matter do you find in the Rivington waters before filtering them?—I have here a great number of analyses with me, and the highest is 2·59; that is from a stream whence the water was taken in a time of drought, and hence the earthy salts and other matters were in great abundance in proportion to the quantity that was flowing down, but taking the water from the reservoir it was 1·12.

2293. What was the quantity of organic matter at the reservoirs at Liverpool?—I am not able to speak to that off-hand, but I think it does not exceed 2.

2294. Do you know whether it loses any of that in in the transit from Rivington to the reservoir?—I should say not; it is very much the same in quality.

2295. The quantity of organic matter in the water from the wells I see you have taken at 0·7?—Yes.

2296. But the wells contain, do they not, a larger proportion of inorganic matter?—Yes.

2297. The chief cause of the hardness of this well water, I perceive by the paper which you have placed in my hands, is sulphate of lime?—Yes, that is the hardening quality.

2298. And the chief cause of the slight degree of hardness in the Rivington Pike water is the existence of carbonate of lime?—Yes, carbonate of lime and a little magnesia.

2299. Have you found that the mixed waters, which you now deliver in Liverpool, have any effect upon the lead pipes?—No, the pipes become coated inside by the earthy salts which are held in suspension.

2300–1. Have you had any opportunity of examining the effects of the Rivington water by itself upon lead pipes?—I have not, but I believe that after the lead is once coated over the water has no effect whatever upon it; after passing water down through a new pipe or a new cistern, the action of the water on the lead ceases in a very short time.

2302. At first you imagine that the water does act upon the lead?—At first chemists tell me that it has an action, but I have not found in practice that we have that continued action.

2303. (*Col. Harness.*) What does the capacity of your catchment reservoir at Rivington amount to?—3,180,000,000 gallons.

2304. Can you tell me what that is in inches of rain?—I cannot tell you off-hand.

2305. I see that the quantity which you return as compensation is the same in every year; are you always giving out compensation?—Constantly.

2306. Whether the river wants it or not?—We are bound to give it out; if we do not do so we are under penalties, and we have had to pay those penalties.

2307. Supposing the river were in flood, would you still be giving it from your reservoir?—We have always done so.

2308. Then every day you give out a definite quantity of water from your reservoir?—Every day, except in the case of the gauge at Roddlesworth, which we have succeeded in purchasing, 1,800,000 gallons a-day, and there we do not give out water on Sunday; from 6 o'clock on Saturday evening up to 6 o'clock on Monday morning the sluice gates are shut down.

2309. Then you are sometimes increasing the flood?—Yes, if there is a succession of heavy rains, and our reservoir is full, we should let the water down just the same.

2310. Does all the water come into your reservoir?—All the water of those streams that we take when we impound them.

2311. Therefore there is no flood in the river unless your reservoirs are overflowing?—In that part of the river immediately below our embankment there would be no flood unless we let it out.

2312. But below your embankment it might be in flood?—Below our embankment it is frequently in flood.

2313. From other streams might it be in flood?—From other streams it might be so.

2314. But you would still give them the 8,300,000 gallons?—We must do so.

2314*a*. How do you measure the quantity which runs to waste, is it by calculation or measurement?—By calculation over the waste weir, but the quantity which we get from the district for the use of Liverpool is measured into the reservoirs, where we have the means of measuring it. That which passes over the waste weir I calculate in this way: I know whenever the river is in flood, and when we are running to waste, that we are passing down into the reservoir all the rain which falls during that time.

2315. Because you assume that at such a time there is no evaporation?—There is neither evaporation nor absorption, because the quantity of rain has so saturated the ground that it comes down very much like water from a slate roof.

2316. Your calculations are based upon your readings of your gauges?—Yes.

2317. (*Sir B. Phillips.*) You had a good deal of cholera last year in Liverpool, had you not?—We had a good deal of cholera.

2318. Have you any idea from the reports of the medical officers as to the influence of the character of the water upon the health of the town?—Excepting those documents which I have handed in I have no other means of arriving at a theory on that question.

2319. Have you yourself considered the subject in any way?—I have looked at it and regarded it with some degree of anxiety. I was very anxious that the water should be of the best and purest quality and most abundant in quantity during that time, so that places could be kept clean.

2320. (*Chairman.*) Was the outbreak of cholera in your judgment due at all to the insufficient supply apart from the quality of the water?—It is very difficult to say what it was owing to; no doubt if there is a scarcity of water it will influence the state of the public health and the outbreak might have been partly due to that, but I would not venture to say that it was so.

2321. I suppose in Liverpool especially you import

a large amount of disease?—We do; it has a peculiar population.

2322. (*Mr. Harrison.*) Having investigated the whole of this subject for the corporation, and looked at all the various sources of supply, have you come to the conclusion that Bala Lake is the best of the whole?—I have.

2323. If that were supplied to Liverpool you contemplate abandoning all your well supply?—No doubt.

2324. Would you also contemplate abandoning the supply which you now get from the Rivington Waterworks?—That would be a question for the corporation to deal with. My own private opinion is this, that we could sell a large portion of the yield from Rivington to the districts which we pass through. I know that at this moment St. Helen's would be very glad to take a very considerable quantity from us. I believe that Warrington is also short of water and Wigan has a supply of its own, and whether they might be inclined to come to an arrangement with us I do not know, but coming along the district I have no doubt that we could get rid of all the Rivington waters.

2325. Taking it that Bala Lake is about as pure and soft as any water, have the corporation endorsed your views that Bala Lake is the best place to take it from?—There is a division of opinion in the corporation upon that subject, some thinking that there is no need to go for water to Bala or to any foreign source, that we have plenty of water from the red sandstone. Unfortunately I differ from them in that respect. Others again think that the time has not yet come for going for such a large scheme. There again I differ from them. They might be inclined to go for a large scheme if they could see a pressing necessity for it, but I have had this subject constantly before me for a length of time, and I have come to the conclusion that if Bala is not taken for Liverpool other parties will come forward and take it.

2326. Then perhaps the view of the corporation may not be one so much as to the quality of the water as to the actual cost which they would have to incur to bring it?—I have no doubt that that has great influence over their views.

2327. But in your mind there would be, I presume, from what you say, a great advantage in having the pure and soft water of Bala Lake delivered into the town of Liverpool generally?—I have no doubt about it.

2328. Have you contemplated at all in your scheme supplying any other towns in the course of the pipe?—I have thought of Chester and also of Birkenhead. It is quite possible, from the line below the reservoir, near to Llangollen, to supply those towns. Indeed, I may state further that a project was in Parliament a short time ago for carrying a tunnel under the Mersey, and I have thought that if the scheme could be accomplished the main pipe might be taken down that way.

2329. That is not done yet, you know?—No, it is not done; but still the other way is open, and hence I have proposed the other way.

2330. Still, at the elevation at which your pipe would be and your head of water, you would be able to supply a great number of those places which come within range of it, especially as they are only small towns?—No doubt.

2331. Crewe is a large place, as we know, and Warrington is pretty well supplied, is it not?—No; Warrington is not very well supplied. I had occasion to be in Warrington some time ago, and investigated their supply, and I know that they have it in contemplation to go further to obtain new supplies, which is a certain proof that they require more water.

2332. When you calculate, no doubt cautiously, upon an available supply from about 18 inches of rainfall in this district, do not you think that that is rather low, although it may be perfectly safe?—I have done it simply to avoid committing an error which has proved fatal to a great many waterworks projects. I know I am within the mark; and I know this also, that what water we do not require would still go down the rivers.

2333. But if more water were required than what you are taking you still have the means within the district of adding a larger watershed to your supply, and even to double it?—I know no district with such capabilities.

2334. You have merely included a certain area, and if it had been desired you might have doubled or trebled the area of watershed and brought it into your conduit from that district?—Yes, that might be done easily.

2335. In the case of Loch Katrine they do not filter their water there at all, do they?—No, they do not.

2336. Do they filter it at Manchester?—No.

2337. They have a large number of reservoirs, have they not, in which the water settles, and they draw it off from one to the other?—They have a larger quantity of spring water there than we have in the Rivington district, and they drain that off and appropriate it for the use of the town, giving out the ordinary water for the millowners.

2338. Have you based your estimate upon actual sections taken of the line of the proposed conduit?—I have taken no levels beyond those which I found upon the Ordnance map. I know what the level of the lake is, and I know what the level of the Dee is down at Llantisilio by the Ordnance map. I also know from observation what the level of this reservoir would be, because I have allowed a certain fall per mile, the ground being of a sloping character, and I have walked over the ground and fixed upon this spot. I also know the levels at the several other points along the route, but I have not made any actual section. I believe that at the time when Mr. Rawlinson proposed the Dee scheme—what is termed the Bala Lake scheme—he had sections made over the whole area, but I have not been able to obtain a sight of them. However, I know that between the various points I am quite correct, or at least as near as may be.

2339. Have you seen the scheme that is proposed by Mr. Hemans?—I have.

2340. He proposes to take water from the lakes of Westmoreland and Cumberland, and in his plan his main conduit comes over the lower part of your Rivington works and at a level of 30 feet above them, does it not?—Yes.

2341. If such a scheme were carried out, and he were to deliver water into your pipes, would that answer your purpose equally well?—It would answer my purpose, no doubt, so far as the mere delivering of the water is concerned, but that water would be delivered 24 miles from Liverpool, and we should have a line of pipes to lay down to convey that water over a series of coal fields, extending from the base of our works, I may say, on to within eight miles of Liverpool.

2342. We know that in the Wigan district as you go over the surface of the ground it is nothing but a series of pools of water. Do you find much difficulty in maintaining your pipes there?—Yes, I have found a great deal of difficulty. At this very moment the subject is before the Water Committee; we have a tunnel in the neighbourhood of Rivington about three miles from it. The owner of the Minerals has applied to us to know whether we will purchase the coal under the tunnel or not, and I have had it in serious consideration whether I shall not get another line of tunnel, lay pipes in it, abandon the old line, and let them take the coal as fast as they like; so long as we have our pipes and can get down to them, we can always keep them on something like a level, and even if they are not very level, so long as there are no air locks, we are perfectly safe, but as any party passing under may break the tunnel in working the coals underneath, and may let our water down into the mine, and cut off our supply, then it becomes a very serious question.

T. Duncan, Esq.

1 March 1867.

2343. In Staffordshire, in the case of the canal belonging to the North Staffordshire Railway Company, they had to pay, had they not, for one single seam of coal, upwards of 20,000*l.* as settled by arbitration?—I think so; my estimate of the cost of the coal under this three-quarters-of-a-mile tunnel will amount to several thousand pounds, certainly from 5,000*l.* to 7,000*l.* We have, I may say, purchased at several points, where there are faults, small pieces of coal, so as to let the ground down easily.

2344. Have you yourself, living in Liverpool, ever happened to have stayed for a length of time in a district where you got very soft water, in Manchester, for instance?—Yes, I have lived for some time there.

2345. Have you found a difference between the waters?—I like soft water better than hard. I have lived where I have had nothing but rain water. During the time that I was with the late Mr. Walker in the Fern Islands I had nothing but rain water for seven months together, and liked it better than the water on shore, after I got accustomed to it.

2346. Has the question of the quality of the water been a subject of discussion with your town council, as to the hardness or the softness of it?—Not so much that, as whether it is to be a supply from home sources; the quantity, if I am not mistaken, has been the great object and the price. There are many gentlemen in the council very desirous, and indeed I believe they are all very desirous, of seeing the best quality of water, but they consider the red sandstone water the finest quality water for table use in the world, although it is not by any means the best quality of water for general purposes.

2347. You have no Bill this session before Parliament to extend your water supply?—No, I am at present engaged in sinking two wells, in fact I have got orders to sink a third shaft, and put down bore-holes, in order to test more than has ever yet been done the capabilities of the red sandstone around Liverpool, for furnishing an additional supply.

2348. Have you found that the pumping from the red sandstone has diminished in quantity?—My experience is that the water has diminished in the red sandstone; the water line is gradually lowering.

2349. (*Mr. Prestwich.*) There are other wells furnishing now some water, are there not?—There are other wells within our district of supply. We draw altogether, from recent investigations which I had occasion to make, somewhere about 15,000,000 gallons per day of water, which is 1,000,000 gallons to four square miles, and taking 60 square miles as our district of supply, I find from my own experience of the wells which I have under my management, that we are gradually lessening the quantity. At Green Lane well, which is a very excellent red sandstone well, when we had finished our bore-hole, about 1855 I think it was, our yield a short time after that was about 3,300,000 gallons a day. Taking the yield during last year, at the same point, I found it was down at 3,000,000 gallons a day, so that is 10 per cent. off the maximum yield in 10 years, or about one per cent. per annum.

2350. Had any wells in the meantime been constructed in the neighbourhood?—Some others have been constructed; one well has been constructed by the railway company not far from it, but they have not begun to pump from that well.

2351. But are there any wells within a distance to draw water from the same sources of supply?—Not any well of consequence excepting that well.

2352. (*Col. Harness.*) Have any of the other wells increased in the same period?—None of them have increased except at Bootle, which I am now engaged upon. There, by sinking that well from a depth of 30 feet from the surface, I have lowered the body of the well 70 feet, making it in all 100 feet, and I have taken off the head from the bore-holes which yielded the water before, and we have got an increase of water there from about 900,000 to 1,000,000 gallons per day.

2353. (*Chairman.*) Are you sinking two fresh wells?—Yes, we are sinking two fresh wells at present, and another well I am about to sink.

2354. Would not that tax the same source?—They are at a considerable distance from each other, but I am not sure what the effects may be.

2355. What is the extent of the depression of your water?—I find at Bootle that I am obliged to go down somewhere over 50 feet to get the same quantity from a well under similar circumstances. Compared with my former experiment, when we obtained at a certain depth from the surface a maximum supply of so many gallons per day, to get the same quantity I was obliged to lower the water down to take so much head off, so that it would spring up through the bore-holes.

2356. (*Mr. Harrison.*) You have only calculated upon raising the water of Bala Lake to the extent of 5 feet; supposing you required a much larger supply than that which you have mentioned, I presume you would have resort to additional reservoirs up in the hills?—Precisely so. There is one point on the Treweryn stream where we could have 14,000 acres impounded in two reservoirs where the sites are exceedingly favourable, and which would hold as much water as we have at Rivington altogether.

2357. Do you think that the difference in the nature of stratification there would enable you in that case to do with artificial reservoirs without filtering?—I propose to supply as compensation all the water that I would derive there, leaving the lake for the use of Liverpool, and giving the compensation water from artificial reservoirs.

2358. (*Mr. Prestwich.*) Do you know the difference between hardness of the waters in the wells and those from the new red sandstone?—I think it is pretty nearly a constant quantity. There is no doubt of this, that the longer we have worked these wells the harder the water becomes. At first the Green Lane water was somewhere about 4½ degrees of hardness, I think, speaking from memory, and now I believe it is somewhat over 7, so that it has increased.

2359. Is there then any difference in the hardness of the water before and after boiling?—It softens by boiling.

2360. (*Mr. Harrison.*) Do you find during your 20 years' experience of Liverpool that the habits of the people have altered much as to the consumption of water, and also that the large sanatory improvements which have taken place very largely added to the quantity consumed per head?—No doubt they have.

2361. Can you give us what in your earlier period was the consumption per head?—It was about 11 gallons per head per day, about 20 years ago.

2362. It has been gradually increasing?—Yes; it has been gradually increasing as drainage works have progressed.

2363. Do you recollect what the consumption at present is in Glasgow?—It is very large, somewhere near 50 gallons per head, I believe.

2364. Is that wasted?—There is no doubt that a very large portion of that is wilfully wasted.

2365. Do you think that in a large town where sufficient care is taken to prevent waste, 30 gallons per head would be sufficient?—If you have power to prevent waste, I believe that for a town such as Liverpool, 30 gallons per head per day would be about the right quantity. That quantity will no doubt go on increasing as the population increases, and it is very rapidly increasing.

2366. Going back to a period of not more than 10 years ago, was not the regular standard given in evidence by all water engineers before committees a consumption of about 20 gallons per head?—Yes, 20 gallons per head, with which I never agreed, I took it always as being too small.

2367. But still that was the standard?—Yes, that was the standard, and evidence was given before committees of parliament that that was the right quantity to calculate; indeed, some engineers at this day say

that 20 gallons a day is the right quantity, but I cannot agree with them.

2368. Do you feel quite confident, having had that view when 20 gallons was mentioned, that 30 gallons will be sufficient looking at the altered habits of the people?—I should be very sorry to say that 30 gallons will be found sufficient, 25 years after this. I do not say it would. I consider that it is the duty of everyone having the responsibility of obtaining a supply of water for a large community to have a very large margin indeed—over 30 gallons per head.

2369. Has not one of the great sources of increase been the introduction of waterclosets?—Yes.

2370. Another is the introduction of baths?—Yes, and baths also.

2371. And the flushing of the sewers?—Yes, that also is a very large source. It is essential to the health of a town to have the sewers well flushed, to have waterclosets to houses and to have an abundant supply for baths.

2372. Taking the question of the supply of water to London and looking to the probable necessities 20 years hence, the increase in every possible way through sanitary measures and everything else, what should you put, looking forward to those things, as the fair amount per head per day for London, say 20 years hence?—I should say that with the increased population which would be found to exist at that time a larger quantity per head than 30 gallons would be necessary. All our social habits and sanitary arrangements tend to an increased quantity of water being used.

2373. What should you put it at?—I should not be at all astonished if it reached 50 per cent. upon that quantity, making it 45 gallons per head.

2374. In calculating, therefore, upon any large scheme, and looking forward, you would look upon that as something about the measure which ought to be taken as the possible measure?—Somewhere thereabouts. If it is possible to obtain such a quantity. Any district for the supply of London must be capable of being extended far beyond its present wants.

2375. What is the increase in the population per annum in Liverpool or within the district which you supply?—The best proof that I can give with regard to that is the number of tenants that we put on year by year, and taking them at a certain number of persons per house. In 1863 we put on 3,763 new tenants; in 1864, 3,950; in 1865, 3,537. I have not the return for 1866, but the number would be close upon 4,000. Taking them at six individuals per house, you get there very close upon 20,000 persons per annum added upon an area of 60 square miles.

2376. Something like three per cent.?—Yes.

2377. (*Chairman.*) May you not have in the same proportion an increase of customers, or may not parties who are not now taking a supply of water take a fresh supply, so that the proportion does not diminish?—No doubt; still we have gone on so steadily that I am looking to a steady increase year by year of the population, looking to the number of new houses built.

2378. I presume the principle of waterclosets is becoming general?—Yes, the council of Liverpool are adopting that rule, abolishing all cesspools and privies in the town and making what are called trough waterclosets in courts, and many of them take a large quantity of water.

2379. (*Mr. Harrison.*) Looking at such a scheme as this which you are suggesting coming before a parliamentary committee, do you calculate that you would have a considerable opposition from all the millowners and people upon the banks of the Dee, or are there not many rights of that sort to be interfered with?—When I wrote the report, which I have handed in, I was led to believe that we should have a much larger amount of opposition and stronger opposition than I am now inclined to give credit to. I have seen several parties interested in the matter, both landowners and others connected with canals, and I have been told there is less danger of such opposition as I have looked forward to than might be expected.

2380. Would it not add to your parliamentary case whenever you go for your Bill, if you were to include a supply to every town within a moderate distance that could be supplied from this source?—No doubt of it.

2381. And in that case the first portion of your conduit you would make of sufficient size, I suppose, it being an open conduit, to meet any future contingencies, or so construct it that by adding to the size of it you might look ahead of the quantity of water which it would have to convey at first?—I have provided my conduit for 60,000,000 gallons a day; because in constructing a conduit to convey 60,000,000 and one to convey 30,000,000, the actual expense is not at all in the ratio of the quantity; therefore, I have put down that portion of the work as a permanent one till such time as Liverpool shall be twice as large as it now is.

2382. What made you give up the idea of going to the lake district, was it on account of its being more expensive, or what?—First of all, my attention was directed to Windermere and I found that too low, and when I calculated the pumping, I found the cost would be too great. Then I looked to Ullswater, and I considered that to be a most expensive scheme, from the tunnelling and all the other works, and with regard to Haweswater, the same kind of thing obtained there. Besides, with regard to Haweswater, although the rainfall is greater, yet the natural drainage into the lake is not very large, hence, other works would have to be constructed and there would be long and expensive tunnels, and the distance was too great. Taking all things together, none of the schemes that I investigated presented the same favourable features as the Bala Lake scheme.

2383. (*Chairman.*) Do you at all anticipate opposition from the landowners on the area of your Bala Lake gathering ground?—No, I do not. I do not think that the landowners on the gathering ground unless they are really touched by our works have any right to appear in Parliament against the scheme. The water has passed from them.

2384. What prohibition to secure the purity of the water would you ask Parliament to impose upon the parties owning the land which you propose to pass through?—Simply that they should erect no works upon the streams that would render the water unfit for domestic purposes.

2385. For instance would you prohibit the working of lead mines?—In this district to which I refer, the Bala district, there is not a lead mine. There is one mine worked to a moderate extent, and that is a gold mine. I have looked at the colour of the washings coming down from it, and before they pass 100 yards into the lake all the turbidity is gone, the whole of the matter which was held in suspension has been precipitated, and the water becomes pure.

2386. I suppose a series of settling tanks would get rid of the discolouration and, probably, a great deal of the mischief?—That would get rid of the discolouration, but then there may be other matters in the waters from mines which might render them unfit for domestic use.

2387. Are you aware that some landowners in Wales have had their attention directed to this question of water supply and are under the impression that they have some property in the water?—I am aware of that. I have been spoken to by a Member of Parliament on the subject, and I believe it is his intention to bring a Bill before the House this year to enable him to borrow money to construct reservoirs. If he did so then he would have some property to sell, because he would be impounding the water and saving any community who might go to the district for water of so much expense as they would otherwise be put to, to secure the quantity being retained on the ground for distribution as it might be required; then I think he would have a fair claim.

2388. Did he state to you the terms on which he would be prepared to do that?—No, he only expects to be able to obtain powers to borrow money for that purpose, and I think that might be a legitimate course.

T Duncan, Esq.

21 March 1867.

2389. (*Mr. Harrison*). When he talks of spending perhaps 5,000*l.* in making a reservoir I presume that he cannot have an enlarged idea of what is necessary?—He would be expending that money and saving possibly 5,000*l.* to the parties below, but after the water passes his own estate he has no right in that water.

2390. (*Mr. Prestwich.*) Have you made some estimate as to the cost of getting the water from Bala Lake to Liverpool?—I have estimated it at 1,500,000*l.* That includes the purchase of land for the line of pipe and for the conduit, making a conduit capable of conveying 60,000,000 gallons a day, and for all the land that would be required for reservoirs along the line and for the pipe line.

2391. How much a mile does that amount to?—The distance is 70 miles. I have taken the pipe line for a 44-inch pipe at 6*l.* 10*s.* per lineal yard. That includes land and other works.

2392. (*Chairman.*) Does it include easement as well?—Yes, that includes the whole.

2393. And severance where it occurs?—Yes, all expenses whatever, and I have here the details of the estimate, which I beg leave to hand in.

The witness delivered in the following estimate:—

BALA LAKE SCHEME.—DETAILS OF ESTIMATE.

Estimate for 8-Feet Diameter Culvert.

Section No. 1.

1 yard in loose earth:—	£	s.	d.
Earth excavation, 16 c. yards at 6*d.*	0	8	0
Concrete 2¾ „ 8*s.*	1	2	0
Rubble arching 2¾ „ 12*s.*	1	13	0
Blue brick lining 1 1/10 „ 40*s.*	2	4	0
Filling, trimming, &c.	0	5	0
Land	0	5	0
	£5	17	0

Section No. 2.

1 yard in shaly rock:—	s.	d
Earth excavation, 8 yards at 6*d.*	0	4	0
Rock do., 3·4 „ 2*s.* 6*d.*	0	8	6
Rubble arching 2¾ „ 12*s.*	1	13	0
Blue brick lining, 1 1/10 „ 40*s.*	2	4	0
Asphalte lining, ·458 „ 1*s.* 2*d.*	0	5	6
Filling and trimming	0	5	0
Land	0	5	0
	£5	5	0

Section No. 3.

1 yard in compact rock:—	£	s.	d.
Earth excavation, 8 yards at 6*d.*	0	4	0
Rock do., 2·8 „ 2*s.* 6*d.*	0	7	0
Rubble arching 2¾ „ 12*s.*	1	13	0
Blue brick lining ·55 „ 40*s.*	1	2	0
Filling and trimming	0	5	0
Land	0	5	0
	£3	16	0
Mean of the three Sections	4	19	4
Contingencies	2	0	8
	£7	0	0

Works at Bala Lake:—	£	s.	d
1,320 lineal yards embankment at 40*l.* per yard	52,800	0	0
Byewash, 15,000 square yards at 1*l.*	15,000	0	0
Bridge, 150 yards in length	4,320	0	0
Land, 10 acres at 250*l.*	2,500	0	0
Sluices	5,000	0	0
Tunnel, valves, &c.	2,000	0	0
Walling around byewash and cutting	1,000	0	0
Contingencies	17,380	0	0
	£100,000	0	0

Reservoir at Tryweyrn:—	£	s.	d.
Embankment, 400,000 c. yards at 1*s.*	20,000	0	0
Land, 450 acres at 40*l.*	18,000	0	0
Byewash, sluices, contingencies, &c.	12,000	0	0
	£50,000	0	0

Aqueduct near Llangollen	£50,000	0	0
Aqueduct across the Dee	£25,000	0	0
Aqueduct across the Weaver	£25,000	0	0

Aqueduct across the Mersey:—	£	s.	d.
300 yards at 300*l.* per yard	90,000	0	0
Contingencies, &c.	10,000	0	0
	£100,000	0	0

Estimate for 44-inch iron pipe:

Pipe 1⅛″ thick = 1·08 yard per ton, at 5*l.* 10*s.* per ton.

	£	s.	d.
Cost of pipe per yard	5	1	10
Laying, labour, and material	0	15	0
Land	0	3	4
Contingencies, valves, &c.	0	9	10
	£6	10	0

Elevation at Bala	530	feet.
Fall to Plas Uchaf	36	„
	494	„
Deduct strainers, &c.	20	„
	474	„
Level of Kensington	222	„
	252	„

Length of main from Plas Uchaf to Kensington 53½ miles.
Fall per mile, 4·71 feet.

2394. (*Mr. Harrison.*) Have you a section of the tunnel?—Yes (*producing the same*), I have taken three different sections. I have a very large margin for contingencies of getting over streams.

2395. You do not propose, do you, at any portion of your aqueduct or conduit to leave it open to the atmosphere?—At no place, because the rain water flowing down the slope as it must do in heavy floods and thunder-storms, would get into the conduit and contaminate the water which would otherwise be pure.

2396. What is your fall per mile?—18 inches. I have handed in a sketch that I made of it at the time. A part of the work will be in concrete lined with blue brick and cement.

2397. (*Chairman.*) Would you use Staffordshire bricks?—Yes, or I might line it with good bricks of the country, the Welsh bricks, which would come in cheaper and be equally good.

2398. (*Mr. Prestwich.*) What length of tunnel have you?—Of culvert, about 23¾ miles out of 70.

2399. (*Mr. Harrison.*) The greater part of the work would be cut and cover, would it not?—Yes, the whole of it, excepting a short length of tunnel going through about three quarters of a mile at two points, included in the 23¾ miles.

2400. (*Mr. Prestwich.*) What would be the cost per mile of the 70 miles for delivering 60,000,000 gallons to Liverpool?—13,000*l.* per mile for the culvert and one line of pipes, exclusive of the aqueducts, or carrying bridges over rivers. The largest one crossing the Mersey I set down at 100,000*l.*

2401. (*Mr. Harrison.*) What is the length of the aqueduct there?—Somewhere about 300 yards.

2402. And you put that at 100,000*l.*?—Yes, 100,000*l.*

2403. Do you not think that you have made a very liberal estimate for it?—I have made a very liberal estimate for all the works, because I do not wish to get into difficulties. 300 yards I have put at 300*l.* per yard, or 100*l.* per foot, the contingencies I have put down at 10,000*l.* I have had an offer guaranteed for my estimate. I have taken a very liberal view of the whole subject.

2404. Have you at all studied Mr. Bateman's project for bringing water to London from the hills in Wales?—I have looked at it attentively. In fact I knew Mr. Bateman was engaged upon that scheme a couple of years before the pamphlet was issued.

2405. I will ask you as a general question on the

merely physical practicability of the scheme, you do not at all doubt that?—I have no doubt whatever of its practicability.

2406. But you probably have not gone into it in any way that would enable you to form any opinion as to the estimate?—I have not.

2407. Have you at all gone into the matter as to the amount of rainfall which Mr. Bateman has taken and based his calculations upon?—I have looked at it and I think Mr. Bateman is as nearly right as may be, looking at the guages which I have seen.

2408. He has taken 36 inches, although you have only taken practically for Bala about 18 inches. After making allowance for waste do you think that having regard to the different rain gauges that you have examined he might fairly calculate upon 36 inches?—I think he is very nearly right. The district from which he takes his water is better in position I think for collecting water than even Bala, good as Bala is. The water clouds get driven up those valleys and they drop down to the troughs. We are approaching a dry district whereas he has between us and his own position a wet one, and is more likely to receive a very much larger quantity of rainfall than we would.

2409. He states that his calculation of rainfall would be allowing 10 per cent. more than what is now found in the dryest seasons to be the rainfall for the supply of the Manchester Waterworks. You know quite well the Manchester districts, do you not?—Yes.

2410. Comparing those two districts, the Welsh district where he proposes to put his reservoirs and the Manchester reservoirs, do you think they are nearly similar?—I think the Welsh district is the better of the two—the wetter district.

2411. Should you as an engineer have any fear in making an open conduit for a considerable distance for carrying the water with a fall of say five or six inches to the mile, lined throughout with concrete and bricks?—I would perfer it covered for the reason which I stated; that would very much depend upon the character of the country which it was passing through.

2412. Assuming that it was so arranged that there would be no fear of water falling into it, should you be afraid that flowing as it naturally would at the rate of a mile and a quarter per hour, it would freeze in a very severe frost?—That is one of the difficulties which would attend it.

2413. Should you be afraid of an open mass of water which would be 10 feet deep, and perhaps 30 feet wide, and flowing at the rate of a mile and a quarter per hour, freezing?—I have known rivers flowing more rapidly than that frozen. I can remember passing over a river in the winter of 1812–13, which was navigable up to the point where I crossed it, and it was frozen over, and hundreds of people were skating upon it; what has been before, may be again.

2414. (*Col. Harness.*) The Thames was frozen in that year, was it not?—Yes. I am speaking of the Tay at Perth.

2415. (*Mr. Harrison.*) Still, that would not prevent the flow of the water underneath the ice?—No, it would not. Below the surface the water would continue to flow, but the danger would be in the breaking up.

2416. But as regards the mere actual supply it would not be so; in fact no river is constantly frozen over?—That is so.

2417. The actual supplying goes on just the same?—Yes, just so. Of course, when the height is taken from it they cannot deliver the same volume, but they can always deliver water.

2418. You would not be afraid of a body of water in this conduit flowing at the rate which I mentioned of a mile and a half an hour, as affecting the brick bottom?—Certainly not. Our experience is quite sufficient to warrant us in believing that with good workmanship and good material it would be perfectly safe.

2419. (*Col. Harness.*) What is the highest velocity that you would consider safe with a brick lining?—With a culvert such as that which Mr. Bateman proposes, I should not like to see a velocity very much greater than he proposes. It would be very apt to break.

2420. (*Mr. Harrison.*) Would you prefer where the water line is open to adopt the drainage plan of having overflows, or would you prefer one uniform surface?—I would rather have overflows.

2421. Still that is a mere matter of detail in construction?—Yes, take the fall between end and end and divide it, then you get the best fall.

2422. Has it ever occurred to you in the case of Liverpool that letting that town be dependent entirely upon its supply from one single source in time of rebellion or disturbances in the manufacturing districts they might without much difficulty cut off the supply from your town?—It is not a week old, in fact at this very moment I have watchmen upon the reservoirs night and day to prevent parties interfering with the water. I have placed men at all the junction valves through the town, and at all the mains communicating one with the other. But in a usual way we take all the precautions that we can so that the supply of water should not be interfered with.

2423. You do that in the case of Liverpool, but taking London with a probable increase of its population within a few years to 4,000,000, and assuming it to be dependent for its supply upon a single aqueduct, should you consider that to be an objection that would have much weight in your mind?—It would have some weight, for if you take away the supply of water from a city you take the city itself. Both ancient and modern history shows that generals have used that means of taking cities, by cutting off the supplies. The supply of water ought certainly to be so constructed, and so conducted, as that it would be in the least possible danger; but in passing over districts, such as is proposed to be done in any of the schemes which have been promoted for the supply of London, they would be all more or less subject to that danger; and I do not see how London can be supplied with water without some risk. It is impossible I think; you have not got the water immediately adjoining the city—it is not to be got from the chalk I think.

2424. Supposing that to be considered as an objection to be met, would it be met by retaining some of the existing pumping engines, so that they might at any time be used to supply in such a case?—All the pumping engines are near to London, they are not within London—at Thames Ditton for instance; the Lambeth Works and the Chelsea Works are close to London; and any hostile army approaching London would take those points which were most easily accessible, and which, when taken, would have the greatest effect upon the city; and no doubt a good general would turn his attention to that which would have the greatest effect upon the town he was about to take, and would cut off the supply.

2425. Where you have an aqueduct extending over a distance of 180 miles and odd, of course it would be much more easy for a body of men, not in the case of actual war, but people in a state of disaffection, in the same way as in Ireland, they have destroyed the telegraph, to take any point of such an aqueduct, half-a-dozen men, navvies, in the course of an hour's time would entirely destroy the supply to London?—No doubt it is open to that, but that is a very remote contingency I hope.

2426. It is not one that would at all influence your judgment in such a case as the supply of London?—I do not think it would, seeing the necessity that exists for such a supply. If it could be got without being exposed to such risks by all means bring it in that way which is not exposed; but when you cannot do that you must submit to inconvenience and to risk. If any invading army were able to effect a landing in this country and were to march as far inland as to be able to cut your aqueduct, and if they found their way up to the pumping stations in the neighbourhood of London, they would destroy them just as readily as they would destroy the aqueduct.

T. Duncan, Esq.

21 March 1867.

2427. Assume, not exactly an invading army, but a state of disaffection in the country, such as Fenianism or the rebellion amongst the manufacturing population, what would be your opinion?—I think that anything that Fenianism could do could easily be prevented; and supposing that they could do that they could not do a great deal, but of course it would be impossible to say what would be the effect of a revolution in the country.

2428. Still, in your mind, that objection which has been urged would not weigh with you as against the desire to supply London with pure water?—Certainly not. I would take the best supply that is possible to be obtained for London, and that which could be extended at will.

2429. Is your experience in favour of the corporate bodies in large towns having the entire charge of the waterworks for the supply of those towns?—Most decidedly.

2430. Do you find that they take more enlarged views of the subject than private companies?—I do. I am speaking now from a very slight knowledge of companies and from a very extended knowledge of corporations. But judging of the question from my point of view, considering the supply of water to any town to be a duty which ought to be discharged by the governing body of that town, and not by a trading company, I say that in my opinion the corporations of the various towns or other governing bodies ought to have the supply of water in their own hands. The question is so mixed up with the general health of a town that it is almost impossible to separate it from that view of the subject.

2431. (*Col. Harness.*) Do the corporation of Liverpool draw any part of its revenue from the water supply?—None; they pay their debts, keep the machinery in order, and pay their dividends for borrowed money.

2432. (*Chairman.*) Would you say the same thing as to gas?—No, it does not apply equally to gas. Although light is very essential, there are many ways of making light, yet we may have another way of making light, and people can make for themselves. They can burn candles if they do not choose to have gas. Certainly, with our present habits, we should not like to have recourse to another mode of lighting our streets, and where the gas can be obtained by corporations it might have to be administered as at Manchester, where they do administer the gas estate in the same way as they do the water estate. But yet it is not so essential to the welfare of a town; it does not interfere so much with the health of every individual as the supply of water does

2433. (*Mr. Harrison.*) Do you think that we might take it as a general proposition that in all those towns in England where corporations have undertaken to supply the water they are infinitely better supplied than they were before, and better supplied than towns that are supplied by private companies?—I think that the tendency is altogether in that direction. Corporations are more easily influenced than companies who have dividends to draw from their supply of water.

2434. (*Chairman.*) Do you raise your funds in Liverpool by means of rates?—We have a general rate, then we have a rent, and besides that we have a price per 1000 gallons for water supplied for trade.

2435. Is that rent a compulsory rent?—The rate is compulsory; the rent is not compulsory; and yet it is in another point of view, because if a house within the Borough is not supplied sufficiently with water, the medical officer can report to that effect and order it to be supplied.

2436. Have you a scale of charges adapted to the capacity of the house?—Yes we have. It is a percentage upon the rental.

2437. Has the corporation the power to say to A. and B. you shall have a supply of water, but if you decline to have the supply of water you shall pay a rental?—They do not pay a rental, but yet it is in this way; the rate which is 6*d.* in the pound, one half payable by the owner and the other half by the tenant is compulsory. If you have a private well of your own which yields you a sufficient supply of good water, the medical officer or the authorities would not interfere, but if, on the other hand, you attempt to supply yourself with water which is not in the opinion of the proper authority sufficiently good, he can report, and the corporation then have the power of laying on the water and levying the rent in addition to the rate. The rent at the present time is 6*d.* in the pound.

2438. Have they the power in default of the occupier paying, to charge the landlord?—No; in small property we compound with the landlords for the supply of the whole block of property, and then we make it a compulsory thing upon the landlord himself, just the same as the poors' rate.

2439. (*Sir B. Phillips.*) Have the corporation the power of rating every house to this water rate?—Yes, all property, whether warehouse, shop, or office.

2440. Have you, by your Act of Parliament, the power of creating a rate for the water supply?—Yes.

2441. By that Act have you the power of rating every house in the city of Liverpool to the water rate compulsorily?—To the water rate but not to the water rent.

2442. (*Chairman.*) What is the rate?—6*d.* in the pound upon the particular assessment.

2443. (*Sir B. Phillips.*) Is that paid by the tenant or by the landlord?—It is paid half and half.

2444. Supposing persons have wells in their houses and do not require the supply of the corporation, are they at liberty in any way to get away from the rating?—They cannot get away from the rating, from the rent they may, but not from the rate.

2445. In what way do you distinguish the rent from the rating. I take the rating to be 6*d.* in the pound upon the rental, or whatever it may be assessed at, and for that you undertake to supply a house with water? — There is an amazing quantity of water required for public purposes in a town, and whether you have a domestic supply or not the water is wanted for watering streets, flushing sewers, public fountains, and a variety of other purposes. The rate was levied by the Act of 1862 upon the whole town of Liverpool to pay for the water used for public purposes, and 6*d.* in the pound is, the rent for water used for domestic supply.

2446. Then, in fact, you have a double rate?—We have a rate and a rent, but the rent is not compulsory. I need not take the water for domestic supply if I do not choose, but I am bound to pay a rate for my house, or my warehouse, or my office.

2447. (*Mr. Harrison.*) The two together are about 1*s.* in the pound, I believe?—Yes; the rent is variable, the rate is fixed.

2448. (*Sir B. Phillips.*) The one is compulsory and the other is optional?—Yes.

2449. (*Chairman.*) Have you a copy of your Act?—Yes (*handing in the same*). The rating Act of 1862 deals with the question of compound shops and offices; that Act is quite peculiar, it differs from any other. We have several Acts, from 1847 downwards, but none of them affecting the question of rent and rate; there was quite a rebellion in the town upon the subject, and we had to go to Parliament to settle the question.

2450. (*Sir B. Phillips.*) What is the rateable value of property in Liverpool?—In 1866 it was 2,150,167*l.*

2451. (*Mr. Harrison.*) How long have the waterworks been in the hands of the corporation?—Since 1847, 20 years.

2452. (*Col. Harness.*) How do you draw the line between domestic use and trade use?—Where the water is simply used for the ordinary purposes of a household, for cooking, cleansing the house, waterclosets, baths, for the use of horses and carriages when they are used for family purposes, we consider that is domestic use, but where they use the water for any purposes of trade, as in the case of brewers, or where they have horses at hire, or use it for gardens,

such a use as that is not domestic. It is an arbitrary rate fixed by the council.

2453. (*Mr. Prestwich.*) You mentioned just now that the cost per mile, independent of the aqueducts, would be 13,000*l.*, but I see in this estimate, Appendix A., which you give, taking into consideration the cost of the aqueducts, the works at Bala, independently of the reservoirs, would cost 21,400*l.*?—That is the total cost per mile. It is 19,000*l.* per mile, independently of the reservoirs.

2454. With the reservoirs the cost would be 21,400*l.*?—I calculate the works to be done at Bala Lake at 100,000*l.*, and in the details I have taken a certain number of yards, 1,320 lineal yards of embankment, at 40*l.* a yard. There would be some little difficulty in securing the town of Bala and making permanent works, such as a large affair like this would require to be made. The byewash I have taken at 15,000*l.*, at 1*l.* per superficial yard, and the excavation and other works I have compared with some works which I have done elsewhere of a similar character. The bridge is 150 yards in length; I have taken that at 4,320*l.* Of the land I have taken 10 acres as the quantity required at the lake at 250*l.* an acre, as it is rather good land. I have put that at 2,500*l.*, the sluices 5,000*l.*, the extra width of tunnel at the entrances I have taken at 2,000*l.*, walling around the byewash and cutting 1,000*l.*, and the contingencies I have taken at 17,000*l.* over and above the contingency at 10 per cent., as it is a work which no one can very well tell what it will cost before it is gone into. Whatever other errors I might fall into, I was not disposed to fall into an error of estimate.

T. Duncan, Esq.
21 March 1867.

The witness withdrew.

Adjourned to Wednesday next at half-past 11 o'clock.

Wednesday, 27th March 1867.

PRESENT:

HIS GRACE THE DUKE OF RICHMOND, K.G., IN THE CHAIR.

Sir JOHN THWAITES.
Colonel HARNESS.
Alderman Sir BENJAMIN PHILLIPS.
THOMAS ELLIOT HARRISON, Esq.
JOSEPH PRESTWICH, Esq.

THOMAS HAWKSLEY, Esq., examined.

T. Hawksley, Esq.
27 March 1867.

2455. (*Chairman.*) I believe you are a civil engineer?—Yes, I am.

2456. Are you a member of any societies?—Yes, I am a member of a good many societies; but principally a Vice-President of the Institution of Civil Engineers.

2457. We are quite aware that you are a great authority on all matters of water supply; would you be so good as to state to us your opinion on the best mode of supplying the metropolis with water?—That is a very wide question. I shall be happy to give the Commission any information in my power, but your Grace will understand I am sure that having no scheme of my own I can only answer such questions as may be put to me, and upon any questions which may be put to me I will give the best answers in my power.

2458. You are aware that there are two very large schemes which have been brought before the consideration of this Commission, one by Mr. Bateman for bringing water from the Welsh district, and another by Mr. Hemans and Mr. Hassard conjointly to bring water from the lake district?—Yes.

2459. Have you considered either of those plans?—I have perused the pamphlets and I have given such consideration to them as without a survey of the districts I was able to do.

2460. Would you give us your opinion as to the feasibility of carrying out a scheme as suggested by Mr. Bateman?—I presume I must take it that my answers are to be given upon the supposition that no opposition is offered hereafter by the parties in the district, for I am no judge of the opposition which might hereafter arise. No opposition of course can be made before a commission of this nature, and therefore I can only look upon it just as an engineer and suppose for a moment that no opposition arises. I know that there are very large interests down the river Severn, from its very head to the foot of the estuary, who will be greatly opposed, but unless the Commission wish to have any information upon the nature of those interests of course I will not touch upon them.

2461. If you are aware of any opposition that is likely to be made to the scheme, and if you are aware of the reasons which the parties have for their opposition, the Commission would be glad to hear whether you are in a position to tell us that that opposition is well founded or not?—I can give your Grace some information upon some of the questions which are likely to arise, such as the landowners' oppositions and oppositions which may arise from certain towns on the course of the river.

2462. (*Sir John Thwaites.*) When you speak of landowners do you mean the landowners on the gathering ground?—The landowners on and below the gathering ground, and also with regard to the opposition which is certain to arise in regard to, if I may use the word, the capturing of those flood waters from the estuary itself upon the question of scour. At the same time I would much rather, if your Grace will allow me, go into what of course I know more particularly about, and that is the engineering features of the scheme.

2463. We should be very glad to get all the information you can give us upon the engineering features, but of course the success or the feasibility of a scheme must depend very much upon all the opposition which it would be likely to meet with, and whether there was any good foundation for the dislike entertained to the scheme. Of course the last point to which you have alluded, namely, the capturing of the waters as interfering with the scour of the estuary, would be a very important feature in the case, because if the capture of the water were to such an extent as to interfere with the scour of the estuary, and so to be a very serious matter, of course that would go very much against the merits of the scheme?—No doubt. That is, however, a public question. With respect to the taking up of the flood waters generally, from my knowledge of the Severn, and I am tolerably intimate with it, having been constantly employed upon it for more than 20 years, I may say that it would be rather a benefit than otherwise, if considered apart from the difficulties which will arise in the minds of a great many private persons, and those persons will, I am aware, submit their cases to Parliament in a very strong form as to the policy of making reservoirs of such enormous magnitude upon the head of this great river. I am aware that that has provoked very much alarm, though of course as an engineer I am making reservoirs continually, and am by no means an alarmist myself; still where the project is of such an

T. Hawksley, Esq

27 March 1867.

enormous extent and magnitude as this project is, by which it is proposed to impound the waters of 120,000 or 130,000 acres, it must necessarily happen that the landowners on the course of the stream will be greatly alarmed, because if one of those reservoirs were by misfortune to burst I apprehend that, as in the case of the Sheffield reservoir and the Holmfirth reservoir, great destruction would ensue, and therefore I know that this project for impounding water is so large that many great proprietors on the course of the river will be opposed to it, and I know one or two cases in which a very strong opposition will be offered to any project of this nature.

2464. (*Sir J. Thwaites.*) With regard to the general benefit, is it a benefit to the river in mitigating the floods?—With regard to the diminution of the floods on the course of the river, providing a sufficient and proper amount of compensation is given out to sustain the summer flow the removal of those flood waters would be rather a benefit than otherwise in my estimation, but that is a question altogether different from that which occurs at the lower part of the river. Below the river at Tewkesbury the question assumes a different form; there the question of scour commences, and of course the larger the floods the better the scour, and, inasmuch as the estuary of the river Severn is a sandy and oozy estuary, it is very necessary that those floods should be maintained unless other works are made to prevent the deteriorating effect of the removal of the flood waters. It is very necessary that those floods should be maintained in order to carry that oozy deposit out to sea. The entrance now to Gloucester and to the ports below Gloucester is very indifferent, and I may say even precarious, and the maintenance of the channel is not entirely due to the recession of the tidal water, but to the recession of the tidal water, augmented both in velocity and quantity by the mountain floods.

2465. (*Chairman.*) Now, will you give us your opinion of Mr. Bateman's scheme in an engineering point of view. Are you acquainted at all with the rainfall in that district of country?—Not specially in that country, nor am I aware that anybody is. I believe that there have been no sufficient gauges established in that country to determine the average amount of rainfall, but I know a great deal of the rainfall in analogous districts, and I estimate it myself at 45 inches over the whole surface. There are many parts of that district where the rainfall will be much larger, but the areas upon which that larger rainfall obtains will be small, and the average of the whole upon which it would be safe to depend does not in my opinion exceed 45 inches.

2466. Do you believe that an average of 45 inches over the whole surface would be sufficient to give a supply to London?—No, not on the scale which is proposed.

2467. What do you conceive would be the supply necessary for London?—The present supply to London averages a little more than 90,000,000 gallons per diem. The quantity used in the month of largest consumption was 105,000,000 gallons nominally, but that quantity is ascertained from the displacement of the pumps, and from that must be taken for leakage and other losses through the working barrels and other parts of the work quite 10 per cent., so that the actual distribution would probably be about 94,000,000 or 95,000,000 gallons per day in the month of largest consumption.

2468. What is that month?—It varies. July in London is about the month of largest consumption; in other places it is generally about August, but the London population, at least the West End population, goes away about the middle of July, and of course the consumption is diminished by the operation of that cause.

2469. In order to furnish that supply to London, what amount of rainfall would you consider to be necessary?—I should first explain that the 45 inches of rain is only the quantity which on an average descends from the heavens, and that quantity is subject to two deductions. In the first place, we know as a matter of absolute fact that we cannot by any system of reservoirs which it is practicable to construct (I will not say with a reasonable but with a large amount of capital) deal with more than the average of three consecutive years of minimum fall. We know as a matter of experience—and this important fact is verified by large and long-continued rain tables—that in those three years the average fall of rain is almost precisely one-sixth part less than the general average, and I could refer the Commission to any number of long-continued rain tables to establish that fact; but we know also as engineers that practically that is the case. If we take from the 45 inches a sixth of that quantity, that will be $7\frac{1}{2}$ inches, and that would leave $37\frac{1}{2}$ inches as the quantity of rainfall due to the three minimum years. Then from that we have to take the evaporation. Now, the evaporation over a district like that, part of which is lowland and part of which is highland, will be about $13\frac{1}{2}$ inches, and if that be deducted there is the residual quantity of 24 inches, and that may be deemed to be the available quantity. That is the way in which we now make all our calculations for undertakings of this kind. I am not shifting or moving the calculation in any way. This system has been tested by actual results in a great many cases, and is known to be as accurate as anything dependent upon the eventualities of the seasons can possibly be. It is as near to the truth as we can in practice obtain anything.

2470. You stated that 45 inches was the average rainfall over the whole surface from a comparison with districts of a similar character, will you tell us what those districts are?—In the districts which I mentioned of a similar character where rain gauges have been established, at Rivington for instance, on the Liverpool waterworks, we know that to be the case, and generally in the hilly districts of Lancashire which are certainly as near to the Irish Channel as this Welsh district is, and where the rainfall is certainly as great. And I may mention a very important fact within my own knowledge with regard to the lake district from which extensive deductions have, I think, been made in this case. I am speaking now of the Cumberland and Westmoreland lake district. In that case the rain gauge returns lead to conclusions, which according to my view, are not all well founded. I had the honour of making the waterworks of Whitehaven, and I have been considerably concerned in the lake districts, and I was intimately acquainted with Dr. Miller who has been referred to in this case, and who instituted those observations which have been brought into the evidence which has been laid before this Commission; but the object of Dr. Miller, who was simply a philosophical investigator, was not to ascertain the mean rainfall in the lake district, but to ascertain the most extraordinary and abnormal rainfalls, and when those gauges were put up they were put up in very peculiar situations, where it was known that large rainfalls obtained in order to measure them as a matter of science, and after they were put up they were moved half a mile, a quarter of a mile, a mile, and so on with a view of obtaining the largest possible results, and those results were obtained, and consequently that circumstance proves that if a square mile receives that large amount of rainfall it ought not to enter into the consideration of a question like this. I believe it is very possible that the gentlemen who may have used those rain tables are not acquainted with all these facts; these things get into books and then they become relied upon as good and valuable data. They are good and valuable for the purposes for which they were intended, but not for this purpose.

2471. Are we to gather from you that you consider that there would not be a sufficient quantity of rainfall in the district proposed to be used by Mr. Bateman to obtain the necessary supply for London?—No; what I say is this—leaving it entirely to the Commissioners to use the information which I have the honour of placing before them in such way as they like, that to the best of my knowledge and belief not

more than 24 inches could be relied upon as the available, collectable, and usable rainfall of the Welsh district. I may mention to the Commission this fact, that when reservoirs, however large, are made, they become filled, and when they become filled the rain still continues to descend, and that water simply goes over the bye-washes, and is lost. Now the quantity of water so lost is represented by the one sixth which I have taken into account, because as the reservoirs must be made to supply during those three dry years, at the average rainfall during those three dry years, they cannot possibly receive the accumulated waters of the wet years. I have here some important diagrams not made at all with reference to this matter which will illustrate my meaning.

2472. Can you put them in so that they may be appended to the report?—Yes, if your Grace pleases. They will require a little explanation, as they were made for my own use only in my investigation as an engineer, and for the purpose of founding upon them certain formulæ for my own use and practice. This diagram (*producing the same*) represents the rainfall of a wet district, in every year from 1831 to 1865.

2473. To what district does that diagram refer?—This is the Bolton district. I have also another diagram of a Scotch district, the Greenock district (*producing the same*). The red line represents the line of average rainfall. You will observe one case in which a large quantity of water was received above the average in the year 1832. I may mention also that you see the excesses of water at different places above the average and also see the defects marked. In order to have made the excess of the year 1832 available we must have kept a portion of that water till the year when you observe that there was the lowest quantity, and it could not have balanced itself for 18 successive years. In one case you will observe there is a hole, so to speak, of rainfall, in which a little portion might be put, and we may therefore write off a little of the top. Then we go on for two years and we come to another excess; we have nowhere to put that excess. Then in the year following we come to another deficiency. We might nearly put that excess into the former cavity, so to speak. The next year the line of average rainfall coincides very nearly with the actual quantity of rain. Then there are two years of defect, and we can put a little more of the excess into that cavity. Then there comes a year of excess again, and that would very nearly fill the rest of the hollow space, leaving still unused, supposing it could be kept, a portion of the first excess. And so we go on, balancing one against the other until at last we find that it would be 18 years before this surplus rain could be made useful, if we acted upon the principle of making the average rainfall available. We find that in point of fact to be a perfect impossibility, because the reservoirs that would take up that larger quantity of water which is seen in 1831 and 1832, and again in 1852 and 1860, and so on, would be so enormously large (and we can perfectly calculate them) that they could not practically be made, and they never are made.

2474. Will you state to the Commission what you consider now and for a certain number of years would be the supply that ought to be obtained for London?—That depends entirely upon the principle upon which the supply is to be given. The present maximum supply of any month in the last year was about 95,000,000 or 96,000,000 gallons per day of actual water, but the return made upon the principle I have mentioned gives about 105,000,000 gallons per day for the average of the month. When we are speaking of gravitation supplies the actual quantity and not the quantity measured by the displacement of the pumps is taken into account, and we must consider it to be 95,000,000 or 96,000,000 per diem.

2475. Do you think that that is sufficient?—Undoubtedly that is much more than it ought to be if the fittings in the houses were in a proper condition in London. Although the water is given for only a short period of the day the fittings are in such an imperfect condition that the waste is enormous.

2476. (*Sir J. Thwaites.*) Do I rightly understand that, having regard to the whole of the gathering ground suggested by Mr. Bateman, you are of opinion that there would be an average rainfall of 45 inches?—Yes, I think so. But I consider that nobody is in a position at present to pronounce what the rainfall of that district is. I am not myself, and I do not put it as if I were.

2477. I understand from you that you deduct one-sixth, is that for absorption?—No; that is for the loss of water which is inevitable in works of this kind, the loss occasioned by floods going over the waste weirs, and the impossibility of making reservoirs to deal with the wet years.

2478. That would reduce it, would it not, to 37½ inches?—Yes.

2479. Then you allow for evaporation, or is that included in the absorption?—No; we have now got to the yield of three consecutive dry years. I may mention to the Commission by way of explanation that in all cases the extreme dry year is as nearly as possible one-third less than the average, and that the extreme wet year is in all cases as nearly as possible one-third more that the average. Then by means of very large reservoirs (and I will give you the data which I employed for determining the sizes of reservoirs) we can reduce that difference from one-third to one-sixth. But then we cannot deal with the remaining sixth, because the reservoirs would be so enormous, for we should have to impound in them the water of those excessively wet years, and that it is quite impossible to do. I can give a great many instances of the way in which I deal with this subject, and the way in which I have come to this conclusion is this: I have learned experience from a long course of failures; I have had my failures like other people, and I have learned from other people's failures as well as profited by my own; I prick the facts off on a diagram, and then pass a curve through the prick marks, and then I find an equation to the curve; and that gives me a rule which I can employ usefully in all cases, and by continual correction, by new facts, we get gradually nearer and nearer to accurate results.

2480. You stated, did you not, that you allowed from the 37½ inches 13½ inches for evaporation?—Yes; 13½ inches.

2481. That would give you an available rainfall of 24 inches?—Yes, upon which you might in my opinion safely rely providing your reservoirs were made large enough to deal with that quantity.

2482. (*Chairman.*) What sized reservoirs should you think would be large enough to deal with that quantity?—The reservoirs to deal with that quantity should be of a magnitude to store 170 days supply.

2483. What does Mr. Bateman propose?—Mr. Bateman says 120 days, that should be about 170 days on my calculation.

2484. (*Mr. Harrison.*) I think you agree that 24 inches are available also for the supply of mills and everything?—Yes, of course. The quantity to be given in compensation is to be taken off before you get to the distributable quantity, but first of all I was dealing with the available rainfall.

2485. (*Chairman.*) 24 inches is what you have to deal with to supply everything, rivers, mills, and London?—Yes.

2486. (*Col. Harness.*) Your reservoirs must be considered, must they not, with reference to compensation just as much as to the water for the consumption of London?—Yes, certainly. In fact there is no difference between the two cases. You simply let the water off by two different pipes, and if there were no compensation it would all come to London; but if there is compensation then one part goes down the rivers and the other part comes to London, but it is all a mixed quantity to be agglomerated in a consideration of this kind.

2487. (*Chairman.*) Do you consider that there

T. Hawksley, Esq.

27 March 1867.

would be any difficulty in making reservoirs large enough to contain that supply?—I have not an idea upon that subject because I have not been down to the district to examine it. I may say that supposing so large a quantity as 300,000,000 gallons to be necessary, the area of the watershed must according to my view be largely increased. If Mr. Bateman, for instance, has taken 36 inches as being available while I take 24 inches his watershed which I think is somewhere about 130,000 acres must be increased exactly one-half, and that would require a watershed of 200,000 acres.

2488. (*Mr. Harrison.*) Putting aside in the first place all opposition to the scheme, and putting also aside the question of cost for the moment, and looking at it as a mere physical work, do you consider that it would be practicable in an engineering point of view to bring the waters from Wales to London by gravitation so as to deliver them as is proposed by Mr. Bateman at a height of 250 feet above datum?—Perfectly practicable in an engineering point of view.

2489. I presume that not having examined the route which it is proposed to take or not having had an opportunity of examining the site of those reservoirs, you have no data to enable you to give any opinion as to what their cost might be?—I have not any data from observation, but I may mention this that if the quantity of 220,000,000 gallons for London, plus one-third of that quantity for compensation making together 300,000,000 gallons per diem, is to be dealt with the reservoirs according to my view must contain more than 8,000,000,000 cubic feet, and that amount of storage is about 1½ times as much as I think Mr. Bateman has calculated upon. At the same time I think it is fair to mention that I do not know of any necessity existing or probable for bringing so vast a quantity of water to London. The average quantity of water used in London is not more than 85,000,000 gallons per diem.

2490. (*Mr. Prestwich.*) How much is that per head?—That would be as nearly as possible 28 gallons per head. That is on the average of the entire year. I believe that that quantity might be greatly reduced if a better system of fair and proper supervision were introduced by the water companies. The water companies now take no charge of the water after it has left the ferrule of their main pipes, and the waste in houses, consequent upon having imperfect fittings, is very great indeed. In many cases, thousands, nay, I might almost say scores of thousands of cases, the water is supplied into butts and other places where there is not even a ball cock to arrest the waste. Everyone of those receptacles is provided with a waste pipe, and of course when it becomes filled, the water does not overflow except by the waste pipe, it does not annoy anybody, and nobody cares anything about it. I consider that the system of the London water companies, with regard to the care of the water, is exceedingly defective indeed. I have not a word to say for their system.

2491. What do you consider would be a sufficient supply per head?—For all the purposes of London, but that includes many things which are not at present very much in use, I should consider that 25 gallons per head would be an extreme supply. Taking the vast size of the place into account, and the magnitude of the population, there are no great number of trades using water; the trade consumption of London, although considerable on the whole, is a very small proportion of the quantity of water which is distributed, whereas in many towns in the country, where the constant supply has been introduced, and where the trade consumption is large, the average quantity of water delivered is under 20 gallons per head. I am speaking now of cases where there is a good and useful inspection, yet with nothing that is oppressive or invidious.

2492. (*Colonel Harness.*) Can you separate the proportion which is used for domestic purposes, as house supply, from the remainder that is distributed?—We know pretty well that the quantity used for domestic purposes is about 12 or 13 gallons per head per diem. In certain parts of London it will considerably exceed that, as, for instance, in the west-end it is much more, because people have baths in their houses, which are a cause of a very considerable consumption of water, but, then again, that is compensated by the comparatively very small quantity of water which is taken at the east-end of London; certainly there are very few houses in which there is anything like a consumption of 25 gallons.

2493. Then would 13 gallons per head be the average between the two?—No, that would be the average of the whole, not the average between them. I should think there are houses in London, indeed many at the west-end, where 20 or 25 gallons per head, or even 30, would not be too much.

2494. (*Mr. Prestwich.*) Have any experiments been made in any public establishment to ascertain the exact quantity of water, individually, for a large number of people?—Yes, it has been done in a great many cases, and for my own information I put on a gauge at my own house. I wanted to ascertain how much my water cost me per 1,000 gallons, and to compare it with the whole quantity of water in London.

2495. (*Sir J. Thwaites.*) What was the result in your own case?—In my own case the result was, that the water cost me almost 2*s.* per 1,000 gallons. I take great care of the water in my own house, not to allow it to be used unnecessarily.

2496. What quantity per head do you calculate for the inmates?—I forget the precise quantity; I took my experiments in relation to the cost at the time; the actual amount used was not more than 10 or 12 gallons, excluding baths.

2497. That did not include the stable I presume?—No, that is separately supplied.

2498. I understand you to state that 25 gallons in London would be a sufficient quantity per head under proper supervision, including trade and all other purposes?—Yes, including everything, undoubtedly.

2499. (*Mr. Prestwich.*) Have not some experiments been made at some of the hospitals with regard to the quantity per head used?—I do not know, but I have made experiments in former years both at hospitals and lunatic asylums, and generally the consumption is very excessive. There is a large waste, and besides that there is an abnormal quantity of water used for baths in many of those establishments, and the water-closets are badly fitted up; in these the water runs to waste almost continually.

2500. (*Mr. Harrison.*) In your experience have you found that the quantity of water consumed per head has been increasing during the last 10 or 20 years?—No doubt. It has been increasing from the introduction in part of more luxurious habits, and in part of better habits. There are amongst large populations much greater numbers of waterclosets than there were formerly, and there is also a much greater number of baths. The waterclosets if properly fitted and arranged may be kept perfectly sweet with a very moderate quantity of water, but the consumption by baths is very large; very few baths indeed take less than 50 gallons at each time they are used, and a great many of them take more.

2501. Is it at all contemplated that the water companies should exercise such a supervision under any powers to be granted to them?—At present it is not a matter of any very great importance to them, because in some degree they check the waste by putting the water on for only a short period; that to a certain extent checks the waste, although it does not check it entirely; but then they take, I daresay, this view: that if they had a sufficient inspection it would be costly, and they contrast the cost of the inspection with the cost of the coals for pumping the waste, and they have come I believe to the conclusion that they would not gain much at present by instituting a more careful inspection.

2502. Supposing London were supplied by gravitation and with a constant supply, what should you consider safe as the least amount to calculate upon per

head for all purposes?—In my view 25 gallons would be safe; but if you extended it to 30 gallons I think there is no doubt whatever that that would be a superabundant quantity. Of course you must add to the present population and that is a very difficult question because it is quite impossible to take it that London should increase at the rate it has recently done; we know indeed by the census tables of this kingdom as well as of others that the rate of increase is declining. In all countries the rate of increase attains a certain maximum and after that it declines. Put it as it was in England at the period of the greatest increase; the increase I think was a little over 2 per cent. per annum throughout the kingdom in general. Then it declines and it will go down to $1\frac{3}{4}$ per cent. Then in future periods it will be $1\frac{1}{2}$ per cent., and so on till it comes down to a more moderate rate of increase. In England we have had a wonderful stimulus by the inventions which have been made; the introduction of the steam engine and railways in particular and the enormous development of our manufacturing power contributed for a certain period to a most rapid increase of the population, but the increase will not, in my opinion, continue at the same rate; nor is the supposition warranted by the statistical facts gathered in England itself and in other countries as well.

2503. Assuming that your view is correct, and that instead of 36 inches only 24 inches would be available, that would merely involve the question of the additional area to be included and consequently of additional cost in the reservoirs upon that area?—Certainly. That is supposing that the ground in the neighbourhood in which the reservoirs would have to be formed (which I do not know to be) is of the proper height, then it is only the question of cost; and I may remark that if smaller quantities of water are wanted than have been calculated upon in this great scheme of course that must be taken into account too the other way.

2504. In your experience of waterworks all over the kingdom, has your attention been specially directed to the quality of water which is most suitable, all things considered, for a large population?—That depends very much upon the habits of the population and their necessities with regard to trade and manufacturing purposes. In the north of England, in all the coal districts, it is very important, because all the great manufactures of the country are always concentrated where coal is, and it is very important that they should have soft water; and the question of the quality of the water in other respects becomes a minor one. In the metropolis it is very necessary that the water should be a white water, perfectly clear and perfectly free from colour.

2505. (*Sir J. Thwaites.*) Why should it be white in the metropolis?—Because it is so disagreeable and so contrary to the taste of the people to have coloured water; they do not like tinted water.

2506. (*Chairman.*) Is soft water necessarily tinted water?—Soft water is almost necessarily tinted water, and is so with very few exceptions. The soft water generally comes from moors and from mountain districts very elevated upon which there is a large quantity of peat growing, and it is almost impossible to prevent that water acquiring a stain more or less deep.

2507. In those districts in which there is a great quantity of peat, except in times of flood, is not the water a very good colour?—It is, but then it is the flood water which is the significant portion of the whole supply. The ordinary flow of the stream is trivial in comparison with the quantity of water that is carried into the reservoirs during floods. I will give this as an illustration. We know by actual admeasurements upon many works, but I will take the Liverpool Waterworks as a very good instance in point, that the floods are 300 times the minimum quantity of the flow of the stream—that is to say, the daily dry weather quantity of July and August is not more than $\frac{1}{300}$th part of what a flood will bring down in a day, and that is quite a common incident to all those mountain streams. The average of the period of wet weather gives a larger quantity than the minimum of which I have spoken by way of illustration, but the consequence is that if you get, say 100 times the volume of brown water to one part of white water, the white water has very little effect in removing the tint.

2508. (*Mr. Harrison.*) Those are extreme points?—Yes. I have put them so, and only by way of illustration.

2509. Take the water of Manchester as we have seen it in the Queen's Hotel, put into bottles and poured into a glass, do you call that white water?—The Manchester water is very often untinted, but it is also frequently tinted; but the fact is, with regard to Manchester, that a separation to a certain limited extent takes place between the white and the brown water, the compensation water being given out of the reservoirs which are not used for the supply of the town, although they may be used for that purpose.

2510. That is the same plan, is it not, which Mr. Bateman has explained to the Commission that he proposes to adopt in his scheme in Wales, so far as it is available?—Yes, so far as it is available, but it is not generally possible to adopt that plan to any great extent.

2511. Going further into the question of the quality of water, do I correctly gather that your view is that, although in the coal and manufacturing districts soft water is an important matter, you do not look upon it as such in the case of London for instance?—Not importantly so; but I must observe that the harder waters divide themselves into two classes, namely, those waters the hardness of which arises from the presence of carbonates and those waters the hardness of which arises from the presence of sulphates. If the hardness of the London waters arose from the presence of sulphates instead of carbonates, as is the case in many parts of the kingdom, I should consider them very unsuitable; the carbonates, however, are not only innoxious in themselves; but as regards many of the purposes for which water is wanted, they are thrown down when it is heated, and the water then becomes exceedingly soft. Now the London water is very soft water, and all chalk waters are so after they are boiled; for manufacturing and many other purposes water is boiled, and also for many domestic purposes.

2512. To put it in a practical way, if you had the choice in the supply of London with water of the degree of hardness which is now supplied hardened by carbonates, and you had the choice also of taking soft water, such as we will say is supplied to Manchester, to which would you give the preference?—If I could get the water tolerably free from stain I should use the soft water, but if I could not I should most certainly, in the case of the metropolis, use the white water in preference to the brown water.

2513. (*Mr. Prestwich.*) When you speak of the importance of soft water for the coal districts, that is, with reference, is it not to the use of water in steam engines?—No, I did not put it simply with regard to the use of water in the coal districts, but what I said was this, that all our great manufactories using water are located in the coal districts, because, of course, of the economy, which attends their being in the immediate neighbourhood of collieries, it is not because of the collieries, but because of the manufactories. The bleaching, dyeing, calico printing, and a great number of other important manufactures, are all established in this kingdom upon or close to the coal formation, and it is very important to them to have very soft water. It is not merely nor altogether largely, though no doubt very importantly, in an economical point of view that they require soft water as a means of saving soap. That, of course, enters into their calculations as an economical question, but generally soft water gives a peculiar character to the fabrics. Take for instance the wool district—wool which is dressed with soft

T. Hawksley, Esq.

27 March 1867.

water and wool which is dressed with hard water feel quite different. Wool which is dressed with soft water feels like silk, whereas wool that is dressed with hard water feels harsh and unpleasant—they are easily distinguishable. Therefore, all the cloth manufacturers prefer to have soft water.

2514. That is very variable, is it not, with regard to different manufactories; some may prefer soft water, and others may prefer water not so soft?—I do not know any case excepting in the manufacture of beer in which hard water is preferred to soft water. In the manufacture of beer hard water is much better than soft water, especially hard water in which the hardness is occasioned by the presence of sulphates, because that water does not take up the extractive matter from the malt, and, therefore, you get a clear bright amber-coloured beer, whereas, in the other case, you get a thick, glutinous, and dark-coloured beer.

2515. Do you know anything of its value in dyeing?—Yes, in dyeing it is very important, not only that the water should be soft, but that certain things which are very frequently present in hard water should be absent—for instance the salts of magnesia—it is very important that they should not be present in any considerable quantity. It so happens that as regards the Thames water there are neither sulphates nor any important quantity of the salts of magnesia which are generally to be met with in the lias and dolomitic districts of England.

2516. (*Sir B. Phillips.*) I understand you to say that the present consumption of water per diem in the metropolis is something like 95,000,000 gallons?—The maximum consumption is about 95,000,00 gallons, the average consumption is about 85,000,000.

2517. Could the existing companies supply a much larger quantity if it were necessary?—Yes.

2518. Have you any idea as to what quantity they could supply with their present resources?—They can supply 100,000,000 gallons I believe from the Thames, and of course there is much more than 100,000,000 gallons in the Thames. Then the New River Company's resources are a little over 30,000,000, and the East London Company has as nearly as possible 20,000,000 gallons, but it is very difficult to say what the Kent Company can derive from their wells; they have wells in two or three positions, and I suppose they might derive perhaps 10,000,000 gallons, it is impossible to say exactly, but we might put that as the maximum.

2519. (*Sir J. Thwaites.*) Do they take any water from the Ravensbourne now?—No.

2520. (*Sir B. Phillips.*) Those quantities together would make about 160,000,000 gallons?—Yes, of course the London companies can get a very much larger quantity of water by obtaining further powers to pump from the Thames, and there are also large districts of chalk where an immense quantity of water might be obtained. That would be subject to compensation of course. Take the Colne for instance, the Colne is a remarkably fine river; it is now affected to a considerable extent by paperworks, but if the London companies took the Colne and compensated the parties interested in the Colne they would get a minimum additional quantity of about 50,000,000 gallons a day.

2521. (*Col. Harness.*) Are we to understand you that at the present time the existing companies could give an additional supply of 160,000,000 gallons a day without having to go to Parliament for further powers?—No, 160,000,000 gallons is the total quantity.

2522. You mean that it could be increased up to 160,000,000 gallons?—They have the power in their own hands of giving that quantity.

2523. And you think the present average supply is 85,000,000?—Yes.

2524. Without going to Parliament and without being subject to claims for compensation?—Yes.

2525. (*Sir B. Phillips.*) You have given some attention to Mr. Bateman's pamphlet; have you seen Mr. Bateman's figures and his estimate of the cost?—I have. I do not presume to imagine that Mr. Bateman put it as exact, but I have no doubt he has done as I should do if I had a similar project. He has done his best with it; of course he lumps in the rights of the parties all the way through the country where this conduit would come winding through it. All those would have to be considered in detail if this were a Parliamentary project instead of being a popular exposition of an engineering scheme.

2526. I think you say that, looking at it simply as an engineering project, apart from all other considerations, Mr. Bateman's scheme is quite practicable?—I think so, subject, of course, to what I have said with regard to the reservoirs. I have not examined the country, and I therefore cannot offer an opinion upon that point.

2527. Looking at the security of a large city like London, with its growing population, do you think that it would be safe to rely for an exclusive supply of water upon a source so distant as the scheme propounded by Mr. Bateman?—No, I look upon that as being one of the most serious objections, not only to Mr. Bateman's scheme, but to anybody's scheme for bringing water from so great a distance. My attention was called to this subject many years ago in relation to quite a different project, and therefore I may state at once what my views are. In the first place, admitting that you could be sure in all seasons of getting a supply for London of the calculated quantity, there would arise the difficulty of ensuring its arrival here. We know that when water proceeds along channels with a small declivity, in frosty weather, particularly when snow is falling, it gets into a state of semi-congelation, and refuses practically to travel at all; it either moves in the slowest possible way or it will not travel. That, to my mind, is a great difficulty, and I do not see a way of overcoming it unless by means of tunnels or pipes, the cost of which would be enormous, or unless some other means which I do not know of were adopted to prevent that effect being produced. Then another great objection, and I may say that this objection has been practically raised by foreign Governments to schemes of my own under similar circumstances, is this, that those waters might be easily interrupted. I have not much fear of a foreign invasion, although such a thing is possible, but the most probable event is that the water might be stopped or let off in troublous times; it is perfectly impossible to protect a line of that length, and the water might be let out at a period of excitement, such as has occurred several times within my memory—for instance, in 1831 and 1848, and at various other periods, and I think it would be a very great calamity if such a thing happened. I should have very great doubt indeed as to the advisability of bringing water that great distance in channels of the kind which have been proposed. As an engineer, I can say that I believe it to be perfectly practicable, but, as a legislator, if I were one, I should entertain great objection to it.

2528. (*Mr. Harrison.*) In such a case as that, assuming that such a scheme were ever carried out, it could only be done by the whole of the existing water companies being really placed under one management, and could that objection be met by retaining a portion of the pumping engines of the present system to meet cases of emergency like that?—That, of course, to some extent might be so, but I do not think, unless you were quite willing to incur a very considerable annual expense in addition to the ordinary expenses of an undertaking of this kind, that it would be at all feasible or desirable to keep up the present establishments. It must be borne in mind that there is something like 12,000 horse power used in the London waterworks.

2529. You are aware that in Mr. Bateman's scheme he shadows forth the idea that all the existing water companies would be either amalgamated or bought up, or something done with them, so as to unite them into one, and that a large amount of saving would take place from, first of all the saving of pumping, and again from the sale of what would become superfluous property. If that were to do you still say that that

saving would not be realized if the engines were to be retained to meet such an emergency as that which you contemplate?—No; but I can give you some information upon that subject. Let it be assumed that this work increased in the proper proportion—could be executed and all compensations paid and everybody satisfied along the line for something like 10,000,000*l.* or 12,000,000*l.* I do not look upon that *per se*, though it is a large expense as a formidable one; but the next thing is this:—The present net revenue of the water companies is, as nearly as possible, 500,000*l.*, and at the time when this work could be brought into operation it will exceed that; but supposing that those companies could be bought at only 20 years' purchase that would amount to 10,000,000*l.* Then supposing you add say 11,000,000*l.* for works, that would be 21,000,000*l.* Then you add to that that it is impossible to have a constant supply (and it is upon the doctrine of a constant supply that this project I apprehend hangs) without reforming all the fittings and service pipes and so on in London, the cost of which would be, as nearly as I can estimate, and I mention that my estimate has been formed for other purposes, 8*l.* a house, and that would bring out a sum of about 3,000,000*l.* Then we have to add to that again the cost, which would be considerable, of rearranging the present system of piping, because it certainly is not adapted for the new project, and there would be a very considerable amount of alteration required. If you put all that at 5,000,000*l.* that would bring it up to 26,000,000*l.*, and that is, I believe, the very smallest sum for which it would be possible to carry out this project.

2530. (*Sir John Thwaites.*) When you speak of 20 years' purchase is that 20 years' purchase on a valuation or 20 years' purchase on the nominal capital of the company?—20 years' purchase on the net revenue. The way in which these purchases are made, and there are many of them, is this:—First of all, the net revenue is arrived at, then that net revenue is in general multiplied by 20, and in some cases by 22 years' purchase. That gives you a certain capital. Then you have to ascertain whether the property is freehold, and if it is not freehold you make a deduction from that for purchasing up the reserved interests. Then you look to the works and you ascertain whether they are in good and efficient working condition—not whether they are new, but whether they are capable of carrying on the supply permanently upon which the net revenue is obtained—and if you find that they are not in that state but are dilapidated, you ascertain the amount of dilapidation and deduct that. In the next place you inquire whether the works are more than capable of performing the service upon which the net revenue has arisen, and if they are more than capable of doing that you ascertain what the value of the additional capability is, and you add for that, and the total of those amounts forms the sum which is to be given, with the exception of one consideration. You have then to ascertain what is the prospective value, whether the interests of the company prospectively are improving, or whether they are only at a standstill. They are not necessarily improving, although their income may be increasing, and their net revenue may be increasing, if they have to put in a proportionate amount of capital; but if a company has made 6 per cent. one year and in the next by the natural increase of its business, without making any more works they get 6½ per cent., then you must look to that, because that is an undeveloped portion of their interest, and then, according to rules which are very well understood, you add for that prospective interest. Then the result is the net sum which is to be given. After that, of course, comes the consideration as to whether that sum is to be commuted into an annual payment, or whether it is to be paid in gross. But that is the uniform mode, and it is a just one, in which those things are done.

2531. It is a mode of ascertaining, and no doubt it is a simple question the number of year's purchase, but you are putting the revenue of the company upon the same footing as you would put a freehold?—Yes, and that is the principle uniformly adopted. I know no instance in all the great valuations where that has not been done. For instance, it was done in the case of the Liverpool valuation, which is the largest that I am aware of. There is one nearly as large at Manchester, that proceeds in a somewhat different way; but at Liverpool, where Mr. Robert Stephenson was appointed the arbitrator, and in a great many other cases, that system was pursued, and pursued under the advice of counsel, and it has never been questioned.

2532. I am not speaking about the system, I am speaking about the number of year's purchase?—I am speaking also about the number of year's purchase, and if you will look at the rate at which in general waterworks shares are sold in this kingdom, you will find that as a rule the rate at which they are sold exceeds 20 years' purchase of the dividends.

2533. Of course they are subject to competition. Take, for instance, the water supply of London; supposing Mr. Bateman were to bring his water from the district which he suggests, and set up a separate establishment, what then?—There are two observations to be made upon that. In the first place, it may be true that they are subject to competition, but no competition can be established except under the authority of Parliament, and that does not affect the value of the property. In the next place, supposing the property to be transferred under the authority of Parliament, that is to say, supposing an Act were passed by Parliament for transferring those works, it is invariably the practice that the case of competition is by that Act put out of the question; you cannot take it into account, and it would not be admitted in any case at all that you could take the value of competition into account where an arbitration is to take place to determine the value of property, because it is always the value of the property as it exists. The purchaser goes in upon the principle of there being no competition.

2534. (*Mr. Harrison.*) With regard to the question of freezing, what is the actual state of the case now in the New River?—In the New River they have had the greatest possible difficulty on many occasions to keep the town supplied, and that is only a short and a small work, a work which at this period, I suppose, brings not much more than 23,000,000 gallons a day; but for bringing about 23,000,000 gallons a day the New River Company have very considerable reservoirs, none that are worthy of being taken into account in a question of this kind, but by the aid of those considerable reservoirs they do manage with extreme difficulty to maintain their supply during frosty weather.

2535. The New River is for many miles a continuous open conduit, is it not?—It is. I suppose now there are about 18 miles of it open, it has been very much altered from what it formerly was, and very much shortened.

2536. Mr. Bateman in his evidence before this Commission, has stated that his view upon that point is this, that he would make his conduit a series of tunnels and open cuttings, and being where it is an open cutting something like 30 feet wide and 10 feet deep, and with a velocity of about a mile and a quarter per hour, he thought that the temperature of the water coming out of those tunnels and passing over a short distance of open cutting would prevent its freezing?—I believe that if it were possible to put it in short lengths, half in tunnel and half out of tunnel, that result might possibly be obtained, but that would be problematical, because the great difficulty is when the snow is falling. When snow falls into the water it does not melt to the then temperature of the water, but gets into a sort of gluey form, which is very well known, and is a very remarkable obstruction, and then the water proceeds either not at all or in a glacier fashion, very tardily. Therefore it is in the open part of the cuttings where the objection would obtain. But I apprehend it would be quite impossible to make an adjustment of that kind; of course there would be

T. Hawksley, Esq.

27 March 1867.

many tunnels upon the line, but I suppose there would be 20 or 30 miles at a time of open cutting, and it would be natural to me to suppose so, because the line as I understand would follow in some part of its path the course of the Grand Junction Canal, and we all know that the Grand Junction Canal is open for a very much greater length.

2537. But you are aware that the Grand Junction Canal of course takes all the windings of the valley along its course?—So I suppose would this conduit, because if it did not you must substitute pipes or tunnels for open conduit at much increased cost.

2538. The plan which Mr. Bateman has laid before the Commission is that instead of following the windings of the valleys he should prefer to make his line as short as he could, and to make it really a series of tunnels and short open cuttings?—I do not pretend to say more upon that point than what at the moment appears to me to be correct, but this I apprehend would be the effect, the temperature of the air would be say 20 degrees, or it might be very much lower occasionally, say 15 to 25 degrees, the natural temperature of the earth in the tunnels would probably be 50 degrees, but the water would very soon cool the lining of the tunnel or the surface of the tunnel and although it would normally be at a temperature of 50 or 51 or 52 degrees, it would not remain at that, it would be cooled down by the water passing through it, it therefore does not appear to me that unless the tunnels were of very great length, the solution of this difficulty would be attained.

2539. If Mr. Bateman were to carry out his scheme on that principle it might be that that objection would be done away with if the tunnels were sufficiently long and sufficiently close to each other?—It might, but I should not like as an engineer to undertake the work upon the supposition that the result would be found different from that which is realized in practice. Take such a year which I well remember as 1814. I was very young then, but I have a perfect remembrance of it. In that year the frost lasted 13 weeks, in the winter of 1813-14 the Thames was frozen over: not frozen over as we have sometimes seen it of late years, but frozen over quite solid, and fairs were held upon it.

2540. Assuming the surface to be frozen over in one night's hard frost, in such a conduit the snow would no longer of course have any effect?—The freezing over would be rather beneficial than otherwise, but the friction would be greatly increased by the sheet of ice formed on the surface.

2541. That would be a case which you would not dread except in the case of the breaking up of the ice?—When the ice does break up, of course it is a very serious thing, but if it were frozen over, and the snow only came after it, the tendency of the snow would be to operate like a blanket—it would keep it to a certain extent warm, at least as warm as the snow, which would possibly be nearly 32 degrees.

2542. Mr. Bateman calculates that there would always be a fortnight's supply in his reservoirs near London, to be conveyed thence by pipe. Do you think that that would be an insufficient period to meet the emergency of such a case of frost?—Yes. I should think it would. My view is governed by the enormous length of this plan. I understand that it is to be 170 or 180 miles, and it might even turn out to be more on an accurate survey, because of course it would be a very important thing to overcome engineering difficulties by winding round the country if you could overcome them in that way, and that in all probability would add something to the length of the line.

2543. Do you think that that is a difficulty which in your view is insurmountable?—I do not know any mode of overcoming it in such a plan as this to which I have alluded. I should think it is a serious difficulty. What has been suggested, viz., keeping the existing London establishments up, of course would overcome it.

2544. You have also taken exception in answer to Sir Benjamin Phillips to the possibility of their being a disturbance in the country, during which, the pipes being destroyed—you are quite well acquainted with the Paris waterworks, are you not?—Yes.

2545. Do you know whether, when they were deciding upon bringing the water the great distance of length that they have done in Paris, that matter was one which was brought under their consideration?—I do not know at all, but I know that foreign Governments view these things very differently from what we do; they would not, in case of a war, care one straw about the supply of the inhabitants of Paris; they would let them go to the Seine or anywhere else to get water for the town; they would not care about that, but that would not answer in a city like London.

2546. Still, in the case of Paris, that has not been considered a sufficient objection to their bringing the water from a distance of considerably more than 100 miles?—I do not know whether it has been considered or not; they have actually proceeded to bring water that distance, and have completed a large portion of the work.

2547. You stated that your experience of cases in which this point has arisen extended to cases abroad where you have been consulted professionally?—Yes, for instance, Copenhagen is a remarkable case. At Copenhagen I was consulted, and there they declined to go out to a very magnificent lake of comparatively soft water, called the Fure Sæ, although it was only five English miles distant.

2548. Was that on the ground of the fear of the water supply being cut off?—Yes, and being interfered with in other ways which I have mentioned, and they were very desirous to have the water supply within reach and under the command of the guns of the fortifications, and at the present moment they have large lakes formed under the walls into which the water is brought. There are many other cases. I was concerned personally at Warsaw and various other places abroad where questions of this kind have arisen.

2549. (*Mr. Prestwich.*) In Paris they bring the water from two sources of supply by two separate aqueducts, do they not, and I believe they are going to have a third?—They do, but it is a very remarkable thing that at Paris they proceeded upon the opposite principle and went to a great distance for the purpose of getting hard colourless water; they would not have soft water, they might have obtained soft water very much nearer, but so different is the view taken by the chemists of different countries that at Paris they actually went away for the purpose of securing a harder water, containing carbonates under the idea that it was more beneficial for the health of the community than soft water.

2550. They have gone to the chalk districts I believe, 100 miles from Paris?—Yes, one of the places I think is near Sens.

2551. One is in Champagne and the other in Sens?—Yes.

2552. (*Sir B. Phillips.*) Have you ever considered any other scheme for supplementing the supply of water to London?—I have not considered any scheme since about the year 1847, when I had a scheme of my own the particulars of which I will give you and the objections to it. That scheme was to bring water from the Thames near Bray, being between Windsor and Maidenhead a very suitable situation, where the water could have been collected above any large population, (although there are Oxford and one or two other places above, they are very remote and at that distance they would do no harm to the water,) and the country was exceedingly suitable for the purpose of conveying it. The project was this: to bring the water after filtering it, along a covered tunnel to a reservoir immediately under Hampstead, and there to raise it by large Cornish engines into reservoirs and allow it to run down to the works of all the companies, and to deliver it to those companies to be afterwards distri-

buted by them. That turned out to be an exceedingly feasible plan, but then the great objection to it was not only that the companies perhaps would not have received the suggestion, or acted upon it if the work had been carried out, but also that the point at which the water was proposed to be taken was above the Royal domains at Windsor, and there certainly was a very considerable objection to taking any supply from the Thames on that account at a point above Windsor: in fact I do not know how the opposition which would arise from that cause could be met, and after we had made our plans and accomplished the scheme in an engineering sense, we were obliged to give it up, we found that the Court did not receive the suggestion with favour, and we knew that it would be absolutely impossible to carry the measure unless we could have the Court with us.

2553. The great complaint of the London water at present is not the quality of the water itself so much as the polluted district through which it passes?—That, I think, there is the greatest possible amount of misconception upon: there is a great deal of prejudice, not unnatural at all, but still amounting to prejudice, upon that question. I believe, in fact I know that the water of the Thames at Hampton is very excellent water, very pure, very free from organic matter, and that what little organic matter it does contain is of a very innoxious character. But the simplest way of dealing with the Thames, if it be desirable to do so, is, in my opinion, not to take the water higher up, but to deal with the much smaller quantity, and bring the sewage lower down. It would be infinitely better, even if the water companies did it at their own expense, to bring the sewage of Oxford and of those other towns which are of considerable size out of the valley than to take the other more expensive and more objectionable course of deriving the water of the Thames at a higher source. There is no difficulty in purifying the river; and if I may state my view, I will put it in this way, that, whereas in my friend Mr. Bateman's scheme you are dealing with 130,000 acres, the valley of the Thames contains nearly 20 times that quantity. There are 2,400,000 acres in the valley of the Thames, and therefore you are always safe of an ample supply, if proper means be taken, and I am not disinclined to say that the companies ought to do something towards it.

2554. You know very well, I daresay, what the powers given to the present Commission are?—Yes.

2555. You are therefore aware that at present we have not the power of inquiring into the question which you are about to open?—No, I am not going to open any question relating to any other point than the question of the supply of London from remote districts, and the Thames having a remote source, the water must come from a remote source, even if it comes from the Thames. The case of the Thames is only a correlative of the channel which Mr. Bateman proposes to make. If you only purify the Thames you may use a naturally made channel instead of an artificially made one; it is just the same thing in the end.

2556. (*Mr. Harrison.*) Do I understand you to say that the opposition from the Royal domains at Windsor or the Crown would, in your opinion, be sufficient to put a stop to any scheme for taking the waters of the Thames from their sources?—I do not say so now, but at that time it was certainly apprehended that it would be so. From intimations we had then we were led to believe it was considered very objectionable on that ground.

2557. Assuming that Mr. Bateman's plan were carried out of having a reservoir at Stanmore, or the plan of Mr. Hemans of having reservoirs, I think, near Hounslow, would there be any difficulty in having a constant high level supply from such a distance from the point of the delivery pipes in London of the existing companies?—I think not. Of course it is a question of the magnitude of the pipes, and that only. The fact, as regards the piping and the constant supply, is this, that at certain periods of the day, generally between 9 o'clock and 11, in the morning, the quantity of water that is delivered is double the average quantity for the whole twenty-four hours, and consequently the main pipes must be made large enough for that purpose. Where the supply is given on the intermittent system the companies spread the delivery just as they think fit over a great number of hours, as much in one hour as in another, but on the system of constant supply they lose the command of the delivery entirely.

2558. (*Sir J. Thwaites.*) What is your opinion with regard to the constant supply as compared with the intermittent system which is now in operation?—The constant supply is much more beneficial than the intermittent supply *per se*, the difficulty is in changing from the one to the other.

2559. Is that difficulty in the mechanical arrangement in the pipes and taps and so on?—Chiefly so. Of course you must have a different organization from what you have now—in point of fact there is scarcely any organization—and people must submit to the inspection of their premises from time to time, but that need not be unpleasant nor need it be frequent.

2560. Under proper inspection, assuming always that the pipes are equal to the pressure and the taps properly formed for the constant supply, do you think that the health of the public would be promoted by having their supply of water constant instead of holding it in vessels that are unsuited to the purpose?—As regards the poor I have no doubt that it would be so, as regards the middle and upper classes I do not think there is anything in that point, because we all have in our own houses admirable receptacles for water, it is quite immaterial to us.

2561. Even under proper regulations is it not your opinion that there would be a waste of water with the constant as compared with the intermittent system?—No, that I can give the fullest answer to. On the contrary where the constant supply is well managed the waste of water is less than upon the intermittent system. I can give you a very remarkable instance, one among a considerable number, but it is so remarkable in itself that it is worth mentioning to you. A few years ago the City of Norwich Waterworks were transferred from a very old-fashioned company to a new one, by whom the system of constant supply had been accepted under an Act of Parliament, that is to say: it was imposed upon them. They tried to work it upon the old principle, and the consequence was that in a very short time the delivery amounted to 40 gallons per head per diem, and that amount of consumption exhausted all their pumping power. They could do no more and the consequence was that they were obliged to shut off the water at night, and the company fell into a state of ruin; all their efforts were insufficient to check the waste, and the work was very nearly being closed. I was called in amongst other persons, and they obtained a very good manager, and under my advice they applied for an additional Act of Parliament to enable them to correct the fittings. With some difficulty—for the bill was opposed as is almost always the case, for there is great jealousy about internal inspection, and so on—the bill was carried and it was put into operation, and now and for many years past, although the constant supply has been unfailingly in use, the water is never shut off, and the consumption has descended to 15 gallons per head per diem as compared with 40 previously.

2562. (*Sir J. Thwaites.*) Are you acquainted with the Hull Waterworks?—Yes.

2563. The evidence of the engineer of those works was to the effect that the substitution of the constant supply for the intermittent system had produced a saving of 25 per cent., have you any remark to make upon that?—I do not know what to say about the Hull system. I think that is exceedingly likely, but the Hull system is a very peculiar and exceptional one; there they pump into a standpipe without the aid of reservoirs, and it was very difficult for them to maintain a good supply. I believe they found at Hull that a considerable saving was effected, but I cannot give the amount.

2564. (*Mr. Harrison*). In your large experience of

T. Hawksley, Esq.

27 March 1867.

these matters have you found that where waterworks have been taken out of the hands of private companies and placed in the hands of public bodies, they have generally been used for the advantage of the town more largely than while they were in the hands of private parties?—No, I have not found it so. In general the management by public bodies is more defective than the management by companies, and for obvious reasons. The public bodies in general are more under external influences and are not capable as a rule (there are a few exceptions) of checking waste and the general experience is that the water, is delivered nominally in larger volume but not by any means more effectively by public bodies than by companies.

2565. My question applied more to corporate bodies undertaking works with a more comprehensive system in view than an individual company would have?—No, I think it would not be so, my experience is that with regard to companies the public care nothing about expenditure, and that they are always urging companies to greater and greater expenditure, whilst with regard to public bodies the public are tenacious on the subject of expenditure, and they are always making outcries against extension, and the general experience which I have had is quite to the opposite effect, namely, that companies can be urged to do greater things for the public than municipal bodies, and it is so from that moral cause; it is not because they have any greater difficulties, except those which are produced by external influences.

2566. Take the case of a city of the magnitude of London; any scheme of this sort, if it were desirable, could not be carried out by separate companies I presume?—No, they could not carry out such a scheme, that would be quite impracticable; what they would have to do would be to amalgamate. There are projects of that kind on foot now, I understand, for amalgamating, the gas companies, as has been done in Paris. There is no difficulty in amalgamating, except, of course, that which arises from the settlement of conflicting interests.

2567. There have been many calculations made and published reducing the value of soft water to *£ s. d.*; in your experience you probably have analyzed several of those statements?—Yes, often.

2568. Would you give the Commission the result of your experience upon that?—The result of my experience is this (I am not going to depreciate the value of soft water, because I do not think it is the monetary value alone which is to be taken into account), that there has been the greatest exaggeration upon these subjects. I know a case, for instance, in Lancashire, where an estimate was made of that kind as to the saving of soap, and it turned out upon a critical examination of all the circumstances, that the soap to be saved was double the quantity that had been used. The quantity of water that is used for detergent purposes, except where there are manufactories, is very small indeed, and now since the duty has been taken off soap the question is one of much less importance than it formerly was, and with regard to extractive matters, such as teas and beers and so on, all chalk waters operate just as well as the other waters, inasmuch as they become quite soft in boiling.

2569. Have you looked at the scheme of Mr. Hemans?—Only generally; I can say no more upon that than I have said upon the other. I have only looked at it generally, I know the country.

2570. Your attention has been given, has it not, for several years past, more or less to the question of supplying Liverpool with water from the Bala Lake?—Yes, I had a very great deal to do with that and with the projected supply of Liverpool from a great many other places as well.

2571. In your investigations into the question of taking water from the Bala Lake were there any special circumstances which occurred to you as likely to lead to a strong opposition either from the riparian proprietors or fisheries, or matters of that sort?—I believe that it is quite impossible to obtain the water of Bala Lake; it was all but impossible at that time (1846) if indeed it could be at that time called a Bala Lake scheme at all, for in point of fact it was a River Dee scheme; the water was to be taken about two miles above Llangollen, at a place called Llantisilio, 20 miles from Bala, and instead of being Bala water, the Bala water was only a comparatively small portion of the stream, the river Treweryn, and a great many other rivers came in between; but the first objection to the Bala scheme was the extreme brownness of the water; the Dee is about the brownest coloured stream which I know anywhere.

2572. But the water is not brown in Bala Lake itself?—Bala Lake is very brown, but not so brown as the Dee, and the Treweryn is browner than Bala Lake. But the great difficulties are these. In the first place an immense system of canals is dependent upon that lake for its supply of water. The canals take 20,000,000 gallons a day, and they are unable to part with any of it as the quantity is insufficient for them. In the next place there are the rights of Sir William Watkins Wynne, which he is totally unwilling to part with, and which he possesses under an Act of Parliament acquired since the period I am speaking of, for he was so jealous upon the subject after that endeavour to take the water to Liverpool that he obtained an Act of Parliament himself; those rights are so extensive and he is so powerful that it is not at all likely that anything could be done there without his full consent. Then the next thing is that in consequence of the development of the coal-field down the course of the river Dee, many works have been established and the riparian owners, and especially those who have works upon the river, are very much opposed to the abstraction of the water. Then, again, we come down to Chester, and find the corporation of Chester are exceedingly averse to the abstraction of the water, and then we come to the scour of the estuary, and there the utmost opposition may be expected. I have no doubt that it will be utterly impossible for Liverpool to acquire a supply of water from Bala Lake. But supposing it were worth their while to resort to a more distant source, Windermere is quite open to them, because Windermere is on the margin of the sea, within a very few miles, and there the quantity of water is superabundant, and the rights in the water issuing from the lake are very small indeed.

2573. At Windermere the level is so low that it would require pumping, would it not, when the water was brought to Liverpool?—Yes, but then pumping is not a heavy thing. When I mention that in general the cost of the pumping does not exceed a farthing per 100 feet of lift for every 1,000 gallons, it is not a very large part of the expense. The fact is that pumping schemes cost, as a rule, about one-third of gravitation schemes. Pumping schemes are very much cheaper indeed, even when you capitalize all the cost of coal and labour, and take into account the machinery which is used, every case must however be judged of by itself.

2574. (*Col. Harness.*) Does that farthing include a return upon the capital?—No.

2575. (*Mr. Prestwich.*) It depends upon the length of the aqueduct, does it not?—No, excepting as a question of friction; the friction adds to the head, but except as to that it does not enter into the calculation of the cost of pumping.

2576. (*Col. Harness.*) It includes all the current expenses?—It includes everything connected with the elevation of the water, all the current expenses.

2577. But no return upon the capital?—No.

2578. (*Mr. Prestwich.*) You stated that it was cheaper to supply water by pumping than to bring it by gravitation; but that would depend, would it not, upon the distance which it is brought by gravitation?—Yes. In all cases in which you have to impound water it is the impounding of the water which occasions the enormous cost of the gravitation works.

2579. What would you say in such a case as the New River?—But the New River Company does not impound, except in so far as the reservoir which I

have mentioned is concerned. The New River Company takes the water from the Lee through a measuring instrument, and then passes it down the channel to London without impounding it.

2580. (*Mr. Harrison.*) Just to follow up that question about the Vale of Llangollen, applying your experience in that case to Mr. Bateman's plan on the one hand, or Mr. Heman's on the other, should you anticipate an equal amount of objection to be raised to any scheme which proposed to take water from the Welsh mountains or from the Cumberland lakes?—No, I think not in the same proportion. The rights on the river Dee are very special, and I think the influences which would be brought to bear are more powerful upon the Dee than they would be upon the Severn, considerable as they are upon the Severn.

2581. Taking the Severn, perhaps the number of mills upon it is much less in proportion than the ordinary cases of compensation which are met with in the Midland Counties?—I think the mills are not very numerous, and I think the value of the mills is not very great. It is not an active manufacturing district, and the consequence is that in those districts the mills are generally employed for purposes which are dependent rather upon agriculture than anything else, for instance, in corn grinding and similar operations, those mills are not very important.

2582. With regard to supplying water to London, can you state what is now about the highest level above Ordnance datum to which it will be necessary to carry water for supplying the houses in London?—About 450 feet I should think. I am speaking now as a matter of memory, that is about the maximum, and that would apply to Hampstead.

2583. Omitting Hampstead and Highgate, and a few other places of that description, what height should you say would be sufficient?—I can best put it in this way—the height of the Regent's canal is under 100 feet above Ordnance datum; I will separate the town by the Regent's canal, which is a very good limit indeed, the height of the lofty houses above the Regent's canal—and there are very lofty houses built now—I suppose would be 80 or 90 feet, and if we put it at only 80, that would be 180 feet. Then you have the head that is required to overcome the friction of the pipes. The friction of the leading main is generally about 4 or 5 and in some cases as much as 10 feet per mile, but the friction of the distributory pipe is generally between 16 and 20 feet per mile, and you must add that, supposing you take 50 feet, for the two, it would be 230 feet, and then there would be about 20 feet more for delivery into the cistern, which would make it about 250 feet, so that you may say that for London below the Regent's canal, you would want a head of about 250 feet, and for all above that level you would want a more considerable head.

2584. I think that in that you agree as nearly as possible with Mr. Bateman's view, as to the 250 feet head?—I was not aware that he had given that.

2585. Of course there are places like Hampstead and Highgate to be supplied by pumping?—You must either have more than one system, or you must have a very elevated reservoir to supply the other district.

2586. (*Mr. Prestwich.*) A large proportion of the south side of the town could, I presume, be supplied by a reservoir at a much lower elevation?—The whole of the south side, excepting the neighbourhood of Norwood, Brixton, the Crystal Palace, and similar places could; but the difficulty in all those cases is in having so many different systems.

2587. (*Mr. Harrison.*) Do you know what the height at Norwood would be?—I should think the summit there must be 300 feet. I should not like to pledge myself to any figure, but I should think it is 300 feet above Ordnance datum.

2588. I think it is more than that, say 320 feet, and you would have the height of the house to add to that?—Yes, but I apprehend that all those peaks, which, perhaps, would not have more than 30,000 or 40,000 people upon them, and in their immediate neighbourhood, would at all times be supplied by a steam engine, because it would be very unwise to encounter the enormous cost of providing gravitation for the whole of this large district, in order to accommodate those few by that means.

2589. (*Sir J. Thwaites*) They would require to have a local lift?—Yes, that would accomplish the object in a much cheaper way.

2590. (*Mr. Harrison.*) Taking it into account that the Commissioners are anxious to investigate everything that may be said for this scheme, and also to have before them any salient objection that occurs to your mind, can you suggest anything beyond what you have stated as a really strong point of objection to the scheme of Mr. Bateman?—No, I do not come here to object, nor do I wish to object. I wish to state my independent views upon any subject upon which I may be questioned. Mr. Bateman's scheme is only put before me, I suppose, as an idea for the moment, and I am asked to direct my attention rather to the principle of supplying London from a great distance, than to discuss any scheme in particular; this is only as a mode of doing it.

2591. I am asking you your opinion upon the principle which is involved in any scheme that would have to bring water from so great a distance, whether there is any other objection which occurs to your mind beyond those which you have stated?—There seems to me to be some mistake upon the question of population, and rather a considerable mistake upon the subject of the drainage areas also. How that happens I do not know, but I have had occasion, not connected at all with this matter, to attain an exact knowledge of the amounts of the populations on the watersheds of the Thames, and the Severn, and also of the exact amount of the acreages from which the waters flow. If it be, as I apprehend it is, of some importance to know what those are, I can give the Commission the whole of them. If it be a question of supplying London from a high point on the Thames, it would be useful of course for that purpose. I can give both the rural population and the urban population, with all the particulars of their distribution, both on the Severn and on the Thames. The drainage area of the Severn down to the weir at Tewkesbury, which is the important point, that to which the tide ascends is exactly 2,680 square miles; the exact population in that area is 558,255, and the number of the population per square mile is 208. The valley of the Thames contains 3,656 square miles down to the waterworks above Thames Ditton where the supply is taken; the entire population is 861,302, and the number of persons per square mile is 235; it is a very thinly populated district indeed, in fact there are no minerals in the valley of the Thames, and that is one of the reasons why the Thames water is so valuable, and the population so scanty.

2592. (*Col. Harness.*) If you make the comparison still higher up the Thames, it will be still more in favour of the Thames?—I do not know that comparatively it will be more in favour of the Thames; that I cannot say; but it would be more in favour of Thames water. When I say comparatively, I mean as between the Thames and the Severn.

2593. The population would get more sparse as you ascended the Thames, would it not, than it would as you ascended the Severn?—No, I think not.

2594. (*Sir J. Thwaites.*) Have you any tables with respect to the populations and acreages in a form which you can hand in to the Commission?—Yes.

The witness delivered in the following tables:

T. Hawksley, Esq.

27 March 1867.

Total		861,302

Drainage area, 3,656 square miles, or 2,349,840 acres.
Population, 235·3 per square mile, or rather less than three acres to one person.

I may observe that the way in which these tables are made out is this:—All the Ordnance sheets of the valleys are obtained, and the summit line of the draining area is traced thereon. (*The witness produced several Ordnance sheets, and explained his method to the Commission.*) Where there is any doubt, the spot to which the doubt applies is visited. Upon each one of these sheets the area is taken out, and then they are aggregated together to find what the total is.

2595. (*Col. Harness.*) Would you divide a parish into drainage areas? — Yes, I would, if it is an important and populous parish, as happens to be the case at Wolverhampton. Wolverhampton is in two watersheds, we go down and look at Wolverhampton and ascertain as nearly as possible what numbers of the population there are in each watershed. And as the Commission will see I have used the geological maps for the purpose of arriving at a conclusion as to the value of the sources for water supply, inasmuch as the quality of the water depends upon the geological stratification of the country from which it is derived. I have also a table of the populations located in towns of 2,000 inhabitants and upwards as distinguishing them from little villages, detached farmhouses, and so on.

The witness delivered in the following tables:

TABLE III.—RIVER SEVERN, POPULATION of TOWNS above 2,000 Inhabitants within the WATERSHED above TEWKESBURY.—(See Census, 1861).

Bridgenorth	6,240
Bewdley	2,905
Bromsgrove	5,262
Dudley (part of) say	15,000
Droitwich	3,124

2596. (*Mr. Prestwich.*) With regard to the use of iron pipes in the districts with which you are acquainted in the north of England, where they have a supply of soft water, do you know of any instance in which there has been any action upon the pipes?—The oxidation from the soft water, particularly from those waters that come down from the granites, which are a little alkaline, is enormous, and nothing we know of yet will stop it—it can only be delayed. It is a very excellent thing to dip the pipes in that combination of oil and tar which was patented by Dr. Angus Smith; and there are several other methods, for instance, dipping them in thin Roman cement is very useful, but the water penetrates beneath, and the coatings which are not chemically combined with the iron, and, therefore, are only a temporary protection, become thrown off, and then the oxidation goes on of course just as if the metal had been uncoated. Where the water is soft I always allow two inches for corrosion, that is an inch all the way round, but even that is not in some cases sufficient. The oxidation goes on in a very peculiar form, it begins by forming a sort of carbuncle on the surface of the pipe consisting generally of oxide of iron and some organic matter. Then those coalesce, and by degrees you get a very thick coating.

2597. Have you found it necessary to renew pipes?—Yes, the service pipes, and, with regard to mains, it has the effect of diminishing their delivering power very considerably. But a method which is in fact due to the late Mr. Appold, has been adopted for remedying this latter evil. He contrived a machine by which, in the case of main pipes, you may put a sort of piston into the pipe and put pressure on behind it; that piston moves forward along the pipe, and carries a number of scrapers with it which pare off the oxide, that has been done with considerable success in the case of main pipes, but it is not at all applicable in the case of the distributory pipes.

2598. That would keep the channel clear, but it would not prevent the wear of the pipe?—No, the difficulty about even that is this, that the oxidation goes on, and the water is for a considerable time coloured. Now, the great object of those different processes is not so much for the purpose of preventing the oxidation, although that is a very important consideration, as it is for preventing the water becoming highly coloured with the oxide of iron.

2599. Can you state anything to the Commission with regard to the action of soft water upon lead pipes?—I do not think anything of that. In the first instance, the lead is taken into solution, and you may get by chemical means a precipitate of the oxide of lead combined with the precipitant, whatever it may be; but afterwards the lead is very rarely indeed taken into solution. There is formed an oxide on the surface of the pipe which is insoluble, and the action stops.

2600. Have you had occasion to notice the relative advantages with regard to health in towns supplied with soft water and those supplied with hard water?—There is no difference whatever. The fact is the human laboratory is quite capable of separating from the water that which it does not require, and, of passing it off by the excretory organs, and it does so in all parts of the world. I imagine there are quite as many fine-raced people living in hard water districts as there are living in soft water districts. I am well acquainted with districts of both characters, and I may say that quite four-fifths of the whole surface of the globe yields hard water—in fact, the cretaceous strata and the other lime formations occupy a large portion, from which alone hard water can be obtained. I think these extend quite to four-fifths of the earth's surface.

2601. With regard to this country certainly it is?—And so I think with regard to all the countries that I have visited, and they are not a few.

2602. In speaking of the supply to Paris, the aqueducts there are covered, are they not, throughout their whole length?—I am not quite certain of that, but I believe they are covered most of the way. I know this was proposed; whether it has been carried out, or whether the cost has prevented their being completed in that form, I do not know.

2603. Have you ever gauged the Severn at Shrewsbury on that part of its course?—Not at Shrewsbury, but I have a most minute account of the capabilities of the Severn at its lower portion where it meets the tide.

2604. But not in the upper portion before it receives its lower tributaries?—No, we know very well what the volumes of floods are almost everywhere if that be the question, but I have made no gaugings.

2605. Could you give the Commission some idea of the quantity of water that passes down the Severn above Tewkesbury?—According to my recollection at the moment, the minimum quantity is somewhere about 90,000,000 gallons a day, but that is only after extreme drought. The average quantity is about 1600,000,000 gallons per day.

2606. (*Mr. Harrison.*) Is it not a great deal more than that?—No, it goes down surprisingly. A large part of the country is devoid of springs. It comprises marls and silurian formations. It is wonderful how great a difference there is between the Thames and the Severn in that respect. Mr. Prestwich will know perfectly well what I am going to mention, namely, that a large portion of the districts from which the Severn flows, is marl of the new red sandstone formation, and another portion is silurian. These furnish very few springs, the consequence is, that the flow down the Severn is very small in the summers of dry years, whereas in the Thames the strata being open, consisting of chalks and oolites to a very large extent, the discharge in summer is very large, and hence you get in the Thames a minimum of very nearly 400,000,000 gallons per diem at Teddington Lock, whilst in the Severn you get considerably under 100,000,000. I will not pledge myself without looking at the figures to what the amount is, but the minimum at Teddington Lock is, if I recollect aright, about 360,000,000 gallons in the driest weather.

The witness withdrew.

GEORGE EEDES EACHUS, Esq., examined.

2607. (*Sir J. Thwaites.*) You are a civil engineer, I believe?—I am.

2608. Has your attention been directed to the supply of towns with water?—Not generally, but I have directed my attention to it lately since the pamphlets of Mr. Bateman and others have been published with regard to that question.

2609. Have you ever carried out any waterworks?—No, I have not. It is not to the engineering points of the question that I allude in my evidence, but rather to the general principle, that, assuming other things to be equal, each county ought first to supply the towns in it and in the adjoining counties before the water is taken to any distance.

2610. That assumes that there is sufficient water in each county for the supply of the county itself?—I have taken the acreage of the different counties and the available rainfall in those counties from the best data that I could obtain, and have thus obtained the amount of rainfall that there is in each county.

2611. Do you know anything of the Welsh district from which Mr. Bateman proposes to take his supply?—I have been in Wales and I have taken into consideration the Welsh district and the amount of rainfall available there.

2612. Have you any means of knowing the amount of rainfall which is due to that district?—Only from what is published by Mr. Symons and Mr. Beardmore and others. Additional data upon that subject are wanted in order to be able to give correct calculations. I think it is quite possible that one might make useful calculations to a considerable extent on the principle I have enunciated, knowing the nature and formation of the different counties.

2613. You come here to enlighten us and therefore you ought to have made your calculations first?—I have made them on the available data.

2614. Have you no other information than that which has been published in reference to the rainfall in the Welsh district?—No, I have not.

2615. At what do you compute the amount of rainfall from that district, taking the average?—The average which I have taken is 36 inches; I have taken the rainfall of the different counties and that is the average, and the largest I have taken is 45 inches.

2616. In your opinion is there a moral wrong in taking water from one county to supply the necessities of others?—Unless it has a superabundance.

2617. I suppose that no one would doubt that the district of Wales to which Mr. Bateman points has a superabundance?—In order to test that conclusion I have taken the population from the census of 1861 and the increase of the population during the last 50 years, then, taking periods of 25 years I have calculated the probable population of each county both in England and Wales at the end of those periods, and allowing 30 gallons per head per day I have found the amount of water required for the daily supply of each county. Next taking the acreage and available rainfall of each county I have estimated the amount each county can supply; and comparing these results with the former I have found what counties have a surplus of available rainfall.

2618. When you speak of the population have you regard to that area which Mr. Bateman is dealing with, or do you refer to the population in general throughout the principality?—To the population in general.

2619. But we are speaking now of the given area from which Mr. Bateman proposes to take his supply of water, which at present is very thinly populated?—Yes, and will be for a very large period of time, even for the next 200 years there will be comparatively speaking a thin population there.

2620. Then it is quite clear that there is more water in that district than will be required by the inhabitants?—Certainly.

2621. In addition to the supply of the inhabitants will it be sufficient for the supply of the metropolis?—More than sufficient.

2622. Do you see any objection to taking the supply from that district?—No, it is at some distance, but I think it is the nearest that there is for obtaining soft water in any large quantity

2623. It is the nearest you mean for the supply of soft water to the metropolis?—Yes, if delivered by gravitation and at the requisite height in London.

2624. You have not looked into the engineering scheme I presume?—No, I am not prepared to give any evidence on the engineering. If the Commission wish it I will place a table before them of the calculations which I have made.

2625. (*Mr. Prestwich.*) With regard to the lake district, what is your opinion of the surplus waters in that district?—I find that they will be required for some of the more populous counties, that Lancashire and some other counties will require the surplus water which they will have available. Warwickshire, Lancashire, and Durham will in the course of time be so thickly populated, (if they increase in anything like the same proportion which they have done hitherto,) as to require the surplus water that may be available from the lake district of Cumberland and Westmoreland.

2626. Have you made any estimate of the quantities of water to be supplied from those districts in Wales, and in Cumberland, and as to the needs of the population in the several districts?—Yes, I have done that, and in this way have arrived at the result shown on a map that I have made, on which I have drawn prohibitory lines, because the counties of England north of the one line would require the water that is available from the lake district; and the counties of Wales south of the other line would require their own available rainfall for their own water supply.

2627. That is merely a matter of opinion; but have you any experiments, or have you any estimates upon which you have founded your conclusions which you could lay before the Commission?—I have made a calculation, from information which I have obtained, which would apply to the different drainage areas. (*The witness delivered in a table.*)

2628. (*Sir J. Thwaites.*) In dealing with this question as a practical engineer, as I assume you to be, one would naturally suppose that your attention had been directed to the area from which it is proposed to obtain a sufficient supply of water, and not merely to have taken the population of the several counties as you have done in this table?—It was as a general principle that I went into the matter.

2629. (*Mr. Harrison.*) I gather that your view is that any scheme for taking water either from Wales or from the lake district ought not to be allowed on the ground that all those waters will be wanted in the course of 100 or 200 years for the supply of the inhabitants of the manufacturing districts in the one case, and of the counties in the other?—I do not go to the extent to say that we ought to provide for the wants of a generation 200 years hence, but that we ought to take the water from that district, allowing other things to be equal which can best spare it. I find that North and Mid Wales taking them as counties, (and whether I take them as counties or as drainage areas, the result will actually be the same, because the counties taken collectively include the drainage areas referred to in the scheme of Mr. Bateman, and in the scheme of Mr. Hemans,) I find in that way that North and Mid Wales have in all cases in every county a surplus quantity of water, and are likely to have even if I extend the calculations over a period of 200 years.

2630. On what ground do you base the statement that the waters from the drainage area mentioned by Mr. Bateman ought not to be taken away?—I say that they may be taken away, because there is a surplus, and there will be a surplus available from that district

G. E. Eachus, Esq.

27 March 1867.

which Mr. Bateman refers to, but not from South Wales. Mr. Bateman does not, I think, propose to take from South Wales.

2631. I think that part of his scheme would go over the borders into South Wales, into a part of Cardiganshire?—Although I have drawn that line along the northern boundaries of Cardigan, Brecknock, and Monmouth, I do not mean to say that it should follow exactly those boundaries.

2632. But the line which you have drawn precludes the taking of water from the district of South Wales. Mr. Bateman's area appears to be southward of that line, and you have no objection to some portion being taken south of that line, but you do object to the lakes being taken?—Just so; on account of the population of Lancashire and the other counties.

2633. (*Sir J. Thwaites.*) If I understood you rightly, your former answer was to the effect that you object to take the water from any one county for the supply of another until the inhabitants of that county are themselves supplied; but you go beyond that in your answer now, inasmuch as you say that you object to taking the supply either from the lake district or from that part of the Welsh district for London, which supply may be required for the large and densely populated districts in Yorkshire and Lancashire?—My former answer alluded to the principle on which I based my calculations, and my latter answer gives the results of those calculations.

The witness withdrew.

Adjourned to Wednesday the 10th of April at half-past 11 o'clock.

Wednesday, 10th April 1867.

PRESENT:

HIS GRACE THE DUKE OF RICHMOND, K.G., IN THE CHAIR.

Sir JOHN THWAITES.
Colonel HARNESS.
Alderman Sir BENJAMIN PHILLIPS.
THOMAS ELLIOTT HARRISON, Esq.
JOSEPH PRESTWICH, Esq.

Dr. Lyon Playfair, C.B.

10 April 1867.

Dr. LYON PLAYFAIR, C.B., examined.

2634. (*Chairman.*) What position do you hold?—I am Professor of Chemistry to the University of Edinburgh.

2635. To what other societies do you belong?—I am a Fellow of the Royal Societies of London and Edinburgh, and I am now Vice-President and was formerly President of the Chemical Society of London.

2636. You have no doubt given considerable attention to the subject of water supply to towns?—I was a member of the Royal Commission for the Health of Towns, and was for a long time chemical adviser to the Board of Health in London.

2637. Therefore the quality of water has naturally come under your consideration?—Very much.

2638. Have you made any examination of the water that is supplied to Glasgow by the new waterworks?—I have not made any special analysis of the water, but I have examined the relative effects upon dyeing of Loch Katrine and the Clyde water.

2639. With regard to the water supplied to London, what course did your examination take?—I frequently analysed in former years the water supplied to London, but I have been 10 years absent from London, and have not done so recently.

2640. To what part of London were your inquiries specially directed?—To all parts of the river, high up the river and down as far as the Lambeth Waterworks, and even to London Bridge.

2641. Did you analyse any of the water after it had become the property of the various companies?—Yes, frequently.

2642. How would you describe that water generally?—At that time, 10 years ago, it was becoming impure as it approached London, it was purer higher up, but as it got nearer the metropolis it became too impure to be wholly desirable for drinking purposes.

2643. You are speaking now, are you not, of the water that was found in the river itself?—Yes, and also of the water as supplied to the public.

2644. With regard to its hardness, what should you say was its peculiarity in that respect?—That it is a hard water. It is not so hard a water as is supplied to many places, but it is decidedly hard water.

2645. Could you mention the degrees of hardness?—I can only do so from memory. It averaged from 13 to 14 degrees on Clark's scale.

2646. What is your opinion, first of all, as to the effect upon the general health of the population, and, in the second place, commercially, in the use of hard water compared with soft water?—As a sanitary question, if the water is otherwise pure, I do not think that mere hardness is of much importance as to health, but it is of the greatest importance as regards the economical use of that water, and its comfortable use for the population. The effect of a hard water upon its ordinary detergent use is seen in the waste of soap and the difficulty of washing which washerwomen experience, and they are far more important members of the industrial community than is generally supposed. In the case of a dozen of shirts, all the interests of the cotton grower, the cotton spinner, the weaver, the shopkeeper, and the sempstress, may be represented at about 72*s.*, but the washerwoman's interest in that dozen of shirts is 117*s.* In other words, the washerwoman derives her profit from the dozen shirts by washing three per week for a period of three years, so that her profit during that time is nearly double that of all the other interests combined. Therefore, anything that will promote economy in such an occupation is always of much value, for the industry of the washerwoman is in reality large, although not usually considered important on account of its great division.

2647. I gather from your statement also that the mass of the population would be likely to be more cleanly, and therefore more healthy, if the water were soft, and less soap were used, than if the water were hard, causing a great difficulty in producing lather?—Yes, it is a curious thing that one never washes one's hands in a basin with hard water; where the water is hard you take a small quantity of it in the hand itself, and rub the soap until it forms a lather in the small quantity of water that is in the hand, and you merely use the water in the basin to rinse off that which you have employed in cleansing the hands; but with soft water you use the whole mass of water for detergence, and therefore it is much more effective.

2648. And it is thereby more conducive to health?—Yes, a more thorough cleansing takes place.

2649. So that if it were a question of obtaining either hard or soft water for a population at the same price, you would give the preference largely to soft water, taking all the purposes into consideration?—At a very great difference of price I would give the preference to soft water, because the economy in manufactures is so enormously great with soft water.

2650. Could you give us any illustrations of the

economical use of soft water in manufactures?—I could give an instance to show the great difference caused by even a small per-centage of additional impurity in a water. In the river Clyde there is a dam or weir across the river to dam up the fresh water for the supply of the manufactories; below this dam several sewers come in and deteriorate the water very slightly as regards analysis, but very greatly as regards its effect upon manufactures. A piece of calico, above this dam, although the difference in value of the water is only about half a grain per gallon of impurities, requires four ounces of madder less to bring it up to the same dye; below the dam of course it requires four ounces more, and the difference of that to an ordinary work where they dye 1,000 pieces a day is 1,562*l.* in the year.

2651. Do you mean that that represents the difference between the use of the water above this dam and below?—Yes; the calico printers dyeing with the water above the dam would save 1,562*l.* a year, supposing they dyed 1,000 pieces a day, which is what good works would do, and they would have to spend that money if they used the water below the dam.

2652. Therefore, that is not a distinction between softness and hardness, but a question of purity or impurity?—In this case the deterioration of the water is owing to its containing iron; the water contains half a grain of oxide of iron below the weir more than it does above.

2653. But have you gone into the question of hard water or soft water as regards manufactures?—I have gone into that, and I have been engaged in a trial where a decision was given against defendants, because only half a grain of carbonate of lime, that is chalk, per gallon, was present in the water, and large damages were given in consequence. My own opinion was that the verdict was a mistake; that that small amount of carbonate of lime did little injury to the water for manufacturing purposes, but the opinion of my brother chemists and the opinion of the referee were different.

2654. What case was that?—That was the case of Higginbotham versus the Corporation of Liverpool, in which Mr. Grove, the Queen's counsel, finally acted as arbitrator.

2655. You say you think that hard water is not so good for manufacture as soft water?—No, I do not think it is as good for manufactures, but I think that so small a difference as half a grain of carbonate of lime per gallon is not of much consequence.

2656. Between what is called really soft water and really hard water there is a very great difference, is there not, with regard to manufactures?—Yes, a very great difference for all kinds of manufactures.

2657. (*Col. Harness.*) The question of whether half a grain of carbonate of lime, more or less, would make a difference or not would depend, would it not, upon what quantity there was in the water which contained the lesser quantity; it would be a proportional quantity?—Yes. In the case I allude to the water was tolerably pure, and this small addition was supposed to have damaged it materially.

2658. (*Mr. Harrison.*) Looking at the sanitary question again as regards general health, you appear to divide that question into the water which is used for drinking and that which is used for personal washing?—Yes. I should have explained that in extreme cases I would consider a hard water injurious to health, but in ordinary cases, such as the Thames water, I do not think it injurious to health, if there are no other impurities in the water than the mere differences in the amount of carbonate of lime.

2659. Supposing that you had a choice between a hard water such as is now supplied from the basin of the Thames, supposing it to be free from impurities of sewage and otherwise, and a pure soft water, which should you give the preference with regard to the question of drinking or its use for culinary purposes?—Undoubtedly to the soft water. In all cases I strongly recommend towns not to accept hard water. Within the last three or four weeks I have been consulted with regard to supporting a bill in Parliament for a water supply to a town, and I refused to support it because it had a water with 20 degrees of hardness.

2660. You do not consider that hardness is positively injurious to health, do you?—In some cases hard water might prove injurious, as in calculous affections and in dyspepsia, still, generally, a tolerably hard water may be taken without much inconvenience; but water of 20 degrees of hardness is very hard water, and I would much prefer even for purposes of health that it should be softer.

2661. Taking the water which comes from the springs in the chalk, do you consider that water generally to be prejudicial to health?—No, not prejudicial to health, except in the circumstances which I have mentioned.

2662. Taking the other side of the question, as to the advantages from cleanliness, both with regard to personal cleanliness and washing from the use of soft water, that you look upon as a matter of considerable importance?—Of very great importance.

2663. And you think that it is decidedly conducive to the health of a town, especially amongst the lower orders of the people?—I think it is of very great importance indeed.

2664. From your experience, have you found that in washing clothes there is much difference in the wear between clothes washed in soft water and clothes washed in hard?—There is a great difference; there is much more wear and tear of clothes washed in hard water than those washed in soft water.

2665. Therefore, in that respect there would be considerable economy in the use of soft water?—Yes.

2666. Have you been able to reduce your views to anything like a money value with respect to the difference between hard water and soft water?—I have done so, but it was many years ago, and I am afraid I could scarcely find my notes upon the subject. I made calculations with regard to Manchester once, and if I can find the notes I will supply them to the Commission.

2667. I that case, I presume, you took into account the benefit to manufactures?—Yes, and I also made an estimate at that time of the increased expenditure to the town of Manchester for ordinary washing purposes from the use of hard water as compared with soft.

2668. In the case of Glasgow have you made any calculation at all with regard to that matter?—No.

2669. Are you cognizant of any calculations that have been made upon that subject?—I am not.

2670. During the time you were on the Sanitary Commission did your reports express any decided opinion as to the difference of the value of hard and soft water?—Yes, we took that particularly into our attention.

2671. Will those views be found on reference to the reports of that Commission?—They will.

2672. (*Mr. Prestwich.*) Are you aware of any disadvantages arising to health from the use of soft water?—The only question involved is, that where it is distributed upon the intermittent system of supply, and the pipes are alternately full and empty, soft water may act upon the lead of the pipes, but if the pipes are always full, and the supply is not on the intermittent system, there is very little risk, or I may say, almost no risk from that cause.

2673. In any of the towns that are supplied with soft water, such as Glasgow, or the towns in the Midland counties supplied with water off the millstone grit, have any instances of the deleterious effects of lead come before you?—I have never seen any instances where the softness of the water produced the evil if the distribution were rightly made. I have seen individual instances of lead poisoning equally with hard water where there has been an intermittent system of supply, but the theoretical danger at all events is more common with soft water.

2674. With the constant system of supply, you consider that there would be no more risk in the use of soft than of hard water?—Precisely so.

Dr. Lyon Playfair, C.B.

10 April 1867.

2675. With regard to the effects of it upon iron pipes, are you aware what the action of soft water may be?—I do not think it would have any effect at all if the water were a pure ordinary good water.

2676. (*Sir J. Thwaites.*) When you say it would have no effect, is that because the pipes are constantly charged and so exclude the air?—Yes, so as to exclude the atmosphere.

2677. (*Mr. Prestwich.*) Soft water in many cases has a very marked action upon iron pipes; it has come before us in evidence several times that tubercular concretions have been formed in the inside of pipes through which soft water has flowed; have you any remark to make upon that circumstance?—I should have much more suspicion of the pipes than of the water, in such a case, for instance, that the pipes had bad castings, or had pieces of graphite or some other material in them to allow those tubercular concretions to form, for I do not see why soft water should act upon iron pipes.

2678. It has not been confined to one particular district or to one particular country. A very marked case was made public some years ago at Grenoble, where the plpes had become so clogged by means of the concretions that they had to be taken up after the lapse of a few years, and fresh pipes laid down?—I have never seen that effect in any district supplied with soft water. I know numerous towns that have been supplied for a great many years with soft water, and I never heard that complained of, and no cases of that kind have come under my own observation. Aberdeen is an instance familiar to the Chairman, and I do not remember to have heard of this action there.

2679. (*Sir J. Thwaites.*) Were the pipes at Aberdeen lined?—I think not. They were laid down many years ago before lining was thought of.

2680. (*Mr. Prestwich.*) It has occurred also in the neighbourhood of Cherbourg where they get water from off the granite district; but I am informed that although the effects are occasional they are not universal, and therefore I want to know whether you are aware of any reason why certain soft waters should have that property and others not?—No, I do not know the fact.

2681. Will you allow me to ask you whether in soft water the same proportion of organic matter would not be more injurious than in water of an ordinary degree of hardness, and what would be the effect of the presence of organic matter in such water?—The effect of organic matter in the water depends very much upon the character of that organic matter. If it be a mere vegetable matter, such as comes from a peaty district, even if the water originally is of a pale sherry colour, on being exposed to the air in reservoirs or in canals leading from one reservoir to another, the vegetable matter gets acted upon by the air and becomes insoluble, and is chiefly deposited, and what remains has no influence on health. But where the organic matter comes from drainage it is a most formidable ingredient in water, and is the one of all others that ought to be looked upon with apprehension when it is from the refuse of animal matter, the drainage of large towns, the drainage of any animals, and especially of human beings.

2682. No doubt a large proportion of organic matter of such a nature would be injurious, but in ordinary cases of a river, such as the Thames above London, the action of the aeration of the water would be in that case to destroy any moderate amount of organic matter, would it not?—It would gradually, but such matter becomes insoluble more slowly than the matter of which I have been speaking; and in any case the presence of it is dangerous, and as one does not know the stage to which the oxidation has gone, the presence of any such animal matter in water is always most objectionable. It is impossible to tell at what stage it is by a mere general examination; by a chemical examination you can do so, but the presence of the most highly oxidised form of organic matter when it passes into the stage of nitrate is, I think, quite sufficient to condemn the water, because you are never sure whether it has fully passed into that stage.

2683. Is it not considered that by the time the Thames water, with which London is now supplied, reach the delivery pipes all organic matter is converted into the state of nitrates and nitrites?—I think that the evidence from the cholera of last summer was quite conclusive on that point, that it was not.

2684. That was confined to one particular district, was it not?—Yes.

2685. With regard to the presence of peaty matter in very soft waters, would not the effect of the oxidation which takes place during the flow of the water from a distance be to lessen the aeration of the water, that is to say, to remove the air from the water by the absorption of the oxygen?—Certainly its effect would be to remove the oxygen from the water whilst it was converting it into this insoluble matter, but water is absorptive of air, and it would soon dissolve it again.

2686. Then the condition of aeration would depend, would it not, upon the length of the flow?—Yes.

2687. In a drinking water do you consider it desirable that it should be well aerated?—It is more pleasant and more agreeable to the taste when it is aerated.

2688. What is your opinion with regard to the presence of carbonic acid in water for drinking purposes?—The presence of carbonic acid in water generally gives a pleasantness to the taste; if you soften hard water artificially by Clark's process, and add a little soda water to it, so as to give it some carbonic acid, you find that the flat taste is taken away, and people drink it more freely.

2689. In the supply of water to a large town what should you consider the first and most important object to be attained?—The first and most important object that I would look to is the nature of the gathering grounds, to see that they were of a character which would supply water free from any human contamination, or contaminations of animal matter; the second point that I would look to would be that the water was soft and was fit for detergent and manufacturing purposes; and the next that the storage ground and the reservoirs should be away from any neighbourhood of a city, and that they should always be kept cool, and aerated in an atmosphere where they would absorb no impurities.

2690. Should you not consider the effect of the water upon health for drinking purposes to be a matter of the first consideration?—I should consider it very important, and all the conditions which I have given have referred to this.

2691. Are you aware of any experiments which have been made with regard to the advantages of the use of either hard water or soft water for drinking purposes?—I can only rely upon the experiences of large towns where they have been supplied with hard water, and the supply has been suddenly changed to soft water; of course I do not know of the reverse instances where soft water has been suddenly changed to hard, but in the former cases I never saw any deterioration of health.

2692. Do the returns of the mortality of the towns now supplied with soft water show any improvement in consequence of the use of soft water?—I might mention such towns as Liverpool, for instance, where there has been a very large improvement in the health, but the introduction of soft water was only one of many hygienic improvements which took place at the same time; therefore, the proportion which should be attributed to that is difficult to distinguish from the others.

2693. That probably would be the case in almost all instances where a new water supply has been introduced?—It is; for a new and enlarged supply of water generally arises when a population has become

awakened to the necessity of hygienic improvements generally.

2694. Are you aware that some experiments have been made in France and in England also by Mr. Simon and others with regard to the effect of soft water upon animals?—Yes, upon cattle.

2695. Are you aware of the results of those experiments?—No, I do not recollect them sufficiently to speak of them now; I know that such experiments were made.

2696. You are aware probably that in a decision recently arrived at with regard to the supply of water to Paris, preference was given to waters of a moderate degree of hardness over those of the Morvan and the Loire?—Yes.

2697. Are you aware of any cause for that preference?—I do not attach nearly so much importance to any hygienic decisions in France as I would to our larger experience in this country, for I think that we are far in advance in our knowledge of the hygiene of cities than they are in France; and I do not think that the experience in this country justifies the selection of water of any amount of hardness if you can get soft water. The only fear of danger is as to the use of lead pipes, but the experience of Glasgow, where it was very much apprehended at one time, has shown that there is no practical danger where the pipes are always filled. There has not been a single case where it has been found, as far as I have heard, that any danger has arisen from the soft Loch Katrine water flowing through the pipes.

2698. In the returns from the different towns I see the rate of mortality mentioned, but there is no means of eliciting from such documents any contrast as to the improved condition of the health between the towns supplied with soft and those supplied with hard water?—No. I think you will find in such cases it is very much according to the quantity of water supplied. If you could get returns with reference to the quantity of water supplied per head of the population in each of those towns, you would have a better index of the influence of water than the mere quality.

2699. (*Chairman.*) In 1850 you were examined, were you not, before the General Board of Health?—I do not recollect that I was.

2700. In a report, called a Report on the Supply of Water to the Metropolis, Appendix No. 3, dated 1850, I see on page 76, "Dr. Lyon Playfair examined?"—That must refer to me, but I do not recollect the circumstance.

2701. Are you able at this period of time to recollect the evidence which you gave on that occasion, I do not mean minutely but so as to state whether or not you would generally concur in what you stated at that time?—I do not recollect even the fact that I was examined then, as I have been examined so often.

2702. I see that in your examination you gave analyses of water from different localities on the Thames, and you were asked this question: "You "have probably seen other analyses by other che- "mists; is there a general correspondence in them "with regard to Thames water?" And you said "There is very little essential variation more than "arises from waters being taken at different times "and places, and I here hand in a table of these "analyses." You probably do not recollect those analyses at the present moment?—No, but if I were to look them over probably I should remember them.

2703. (*Mr. Harrison.*) What was the year to which you referred when you were on the committee of the Water Supply of London?—It was a Royal Commission for inquiring into the state of large towns and populous districts; it sat for two or three years, and it gave in its report, I think, in 1846; it was the chief Health of Towns Commission, upon which general legislation took place with regard to the health of towns.

2704. (*Chairman*). I see you are asked this question, "Have you found reasons to modify your opinions as to the domestic value of soft water?" And your answer is "I speak with the force of increased "experience when I say that I formerly greatly "underrated the advantages of soft water;" and then you go on to show the reasons that you had for preferring soft water to hard?—Yes, I am still entirely of that opinion.

2705. (*Mr. Prestwich.*) You have referred to the effect of soft water in the use of dyes; could not that question be looked at in two points of view—one with regard to the economy in the use of the dyes, and the other with regard to the effect of the dyes themselves?—Yes; it has three influences upon dyeing: first, upon the original bleaching of the cotton; secondly, in the waste of the material used in dyeing; and thirdly, in the cleansing or clearing operations after the dyeing is completed; and in all those cases a pure water is preferable to a water containing any hardening matter.

2706. Does not water of a moderate degree of hardness bring out many colours better than soft water?—I have never found it so; I have carefully experimented, and I have found that distilled water brings out the best colours, and in all the experiments that I have made I have found that hard waters do not bring them out so well; but you will get plenty of manufacturers and dyers to tell you differently, and for this reason, that a dyer gets thoroughly accustomed to the water with which he operates, and he uses his materials and his mode of operation to suit that water; and if any other water is brought to him suddenly, seeing he is guided almost entirely by experience, he will get a worse result with a better water, because he is not accustomed to use it; and it requires the experiments of a chemist to elicit those sources of error. Every brewer who has been accustomed to brew with hard water will inform you that hard water is much better, and more suitable for brewing, whereas a brewer who has been accustomed to brew with soft water will tell you that soft water is better than hard; manufacturing use is entirely a matter of experience, in which people suit themselves to the case before them.

2707. Are you acquainted with the experiments of Du Pasquier with regard to the effects upon dyes in using distilled water, river water, and spring water?—No, I am not. I may mention that I was once the chemist to large calico printing and dyeworks, and that therefore my attention has been practically directed a good deal to that question. In early life I was chemical manager to Messrs. Thompsons' calico print-works in Lancashire.

2708. (*Chairman.*) I see in the Report of 1850, Appendix 3, you are asked this question: "Have "you been called on to analyse the Thames water?" And your answer is: "I have examined the "Thames waters as high as Henley, and also that "delivered by the Chelsea and by the Lambeth "Waterworks Companies." Then you are asked: "Will you state the general characteristics of the "Thames water you have examined as to its hard- "ness?" and your answer is: "I have found the "average hardness of the Thames water from a mean "of about 40 observations to be between 13 and 14 "degrees of hardness. I never found it above 16, and "I have seen it as low as 11. It has been stated to "average 16, but I have never found so high an "average, although occasionally it may be so high. "In two or three instances I have found it as low as "11, but this was due to accidental floods." Have you any reason to doubt the correctness of that?—No; that was my impression when I answered that question, I thought it was not so high as 16 or 17. These numbers refer to Clark's degrees, and not to those of Frankland, which have been lately generally adopted.

2709. The next question is: "Have you analysed "the water of the river Colne?" And your answer is: "I have examined various streams at Watford, "and I think the Colne among them. The Thames "has some 17 or 20 tributary streams. They cannot "be soft when the main stream is hard. I examined

Dr. Lyon Playfair, C.B.

10 April 1867.

" the degrees of hardness of the water at Henley " every day for three weeks, and did not find any very " great variation. One day the water was 16 degrees, " but it generally ranged from 13 to 14." Then you are asked: " Then you think it probable that, " as other chemists state, it may reach 16?" and " your answer is: " I think that it does so only " occasionally. I would not take the average of the " Thames water as delivered in London to be more " than 13, varying from 11 to 15." Then you are asked: " It has been stated that the Thames water is " likely to be affected by the sewage, and that about " London Bridge is softer than higher up?" and your answer is: " I should think it would become so by " the mixture of sewage water. In fact analysis " shows the presence of a much larger quantity of " organic matter at London Bridge than higher up " the stream;" have you any reason to doubt that " those remarks are correct?—Those were perfectly correct observations at the time that they were given, but I have had no experience of the Thames in the last 10 years, having been resident in Edinburgh for nearly that period.

2710. (*Mr. Prestwich.*) A large quantity of the water used in London for domestic purposes is boiled before it is used and that reduces the hardness, does it not?—Yes, it reduces it considerably.

2711. (*Sir J. Thwaites.*) You state, do you not, that water of 20 degrees of hardness would be injurious to health?—I have no direct experience that it is injurious to health, but I should not employ it habitually in my family. I do not think it is a suitable water with which to supply a town.

2712. Can you fix upon a degree of hardness which in your judgment would be safe?—If I were selecting for a town and could get it, I would prefer a water of not above three or four degrees of hardness, and I would dislike waters that are higher.

2713. Take the Thames water for example. When you get a mean of 13 or 14 degrees of hardness out of 40 tests, are you of opinion that that water would be injurious to health?—I would not say that it would be injurious to health. I think it would not, but I believe it is a misfortune that a large metropolis like this is supplied with a water so hard.

2714. You think that it would be worth a considerable sacrifice to obtain water of a less degree of hardness?—I think it would, and it would cover a great outlay to obtain water of a less degree of hardness. I think it is a pity that London cannot be supplied with soft water on account of its greater effect in detergence and for industrial purposes.

2715. (*Sir J. Thwaites.*) Do you mean on the score of health?—On the score of health the mere hardness I do not think would be injurious, at least I have no evidence to show that it is injurious. I am not a medical man, and would therefore speak with diffidence on this part of the inquiry.

2716. (*Mr. Prestwich.*) Do not some medical men consider that the presence of carbonate of lime in drinking water is rather desirable than otherwise for health?—I have seen evidence given in cases of water supply not only that it was desirable for health, but that it was absolutely necessary for the formation of the bones. But that showed a lamentable want of chemical knowledge, because the lime required in food does not come from the water but from the solid articles of food taken, and I do not think that the lime in water has any influence on the processes of healthy nutrition.

2717. (*Chairman.*) What is the quality of the water in the Cumberland and Westmorland district, and in the Highlands of Scotland?—It is generally soft where it comes from mountainous districts.

2718. Is there much lime in it?—No, very little generally, but I am not very familiar with the Cumberland district.

2719. The population are generally fine grown people, are they not?—Yes. Our Highlanders are not generally supposed to be deficient in bone or muscle.

2720. (*Sir J. Thwaites.*) Have you formed any opinion as to the advantage of a constant supply as compared with the intermittent system?—I have the greatest opinion as to the advantage of a constant supply in every way. It delivers the water always cool and in good condition; it obviates the necessity for a number of cisterns in badly ventilated houses, and especially in the houses of the working classes, and so prevents a great source of the danger of epidemics which arise from the solution of the polluted atmosphere in the water.

2721. You refer to the receptacles used by the poor to hold their water?—Yes.

2722. Have you had your attention directed to the condition of that water which, in such cases, has been held in those casks or tubs which the poor use?—Yes, I have occasionally examined them, but it is not so much within the power of a chemist to test such impurities on account of the extremely small quantity of deleterious vapours which may be dissolved in the water, and yet which may prove prejudicial to health; but I have had occasion myself to observe in my laboratory that when I was working with any particularly nasty vapour the water of the cistern got to smell offensively of it, and that therefore water is very absorptive and apt to dissolve those vapours readily.

2723. For example, supposing the case of a house where water is retained in the vessels referred to, and the house is badly ventilated, and gases are generated in the sewer and discharged, would not the water absorb a large amount of that gas?—It would absorb it very readily, and in no state can it be introduced more deleteriously into the system than in a state of solution.

2724. Then a system of constant supply would of course get rid of that mischief?—Yes, you would certainly get rid of that mischief; under that system the water is kept in one or two reservoirs common to a town, and at a place free from impurities, and it is delivered in a state in which it is immediately fit for drinking.

2725. You stated in answer to a question that you had not observed any deleterious results on the water from the use of leaden pipes; does that arise from the pipes being coated after the water has been discharged through them for some time?—When lead pipes are alternately full and empty, as they are on the intermittent system, then oxidation takes place and the lead is dissolved; but when the pipes are constantly full there is very little of this oxidation. Any efficient system of filtration removes the lead in solution, for it is but loosely held.

2726. (*Mr. Harrison.*) The water is not the only point conducive to the health of a town, for if we look at Glasgow the death rate in Glasgow is perhaps nearly as high as in any town in the kingdom?—Yes.

2727. And yet they have got the purest water and the largest supply of any town in England?—Yes.

2728. Therefore, we cannot always take the mere question of death rate as an index of good or bad water?—Precisely so; we must look at the overcrowded state of the population, at the climate, and at the habits and occupations of the population also.

The witness withdrew.

GEORGE J. SYMONS, Esq. further examined.

G. J. Symons, Esq.

10 April 1867.

2729. (*Sir J. Thwaites.*) The matter was referred to you for the purpose of ascertaining some points with regard to the rainfall of the Welsh district; are you prepared to give the Commission information upon that point?—I am; I have prepared a report as nearly as possible in the same manner as I did with regard to the Cumberland district; it is not very lengthy, and perhaps I had better read it.

The same was read as follows:—

REPORT ON THE RAINFALL OF WALES, BY G. J. SYMONS, F.M.S.

In drawing up this report I have found it necessary to make it much more voluminous and comprehensive than would at first sight appear requisite, and indeed than I at first anticipated. The principal causes of this extension have been (1) the fragmentary character of the Welsh returns, (2) my earnest desire to make the report as accurate and impartial as possible.

I proceed to explain the steps by which I have arrived at the results shown on the map which I beg leave to hand in.

On examination of the existing returns I found that the longest period for which complete Welsh registers would give the yearly ratios, was nine years (1858–1866); the first step, therefore, was to determine how much those nine years differed from the average of 20 years; singularly and most fortunately, it appears that the mean of this short period does not differ 1 per cent. from the mean of 20 years. This is shown by table I.

The next step was to take out the yearly depth in those 9 years at all stations bearing on the district (whether in Wales or England) and reduce them to ratios, (tables II. and III.) finally deducing from them the mean ratio due to each year.

Then every complete year's observations made in Wales during the said nine years was taken out and the true mean deduced therefrom; table IV. These values are shown on the map (*see Appendix A, T*), by the plain figures *not underlined*. Thus far the process has been almost identical with that adopted in my report on the rainfall in the Lake district, and thus far I think the results may be implicitly relied upon.

To determine the true value indicated by the short period gauges in the absence of standards of reference in the district is a very difficult matter.

If we take the total in the three months at the old established Welsh stations, we obtain the following values:

Station.	Oct.—Dec. 1866.	True mean. Table II.	Per Cent.
	Inches.	Inches.	
Rhayder	13·69	45·13	30
Lampeter	9·86	44·02	22
Hawarden	6·48	25·41	26
Maes y dre	6·88	24·22	28

Bearing in mind the remoteness of all these stations except Rhayader, 29 per cent. seems the most probable value for the district. An important condition is not, however, fulfilled by these stations, they are dry ones, and the average fall at them was only half what it was at Mr. Bateman's six stations. In discussing the Cumberland returns, I had to take 40 per cent. for some of the more mountainous districts and 30 per cent for the less hilly portions; it was therefore necessary to ascertain if the same rule was applicable to the more hilly parts of the Welsh district. The next step then was to take out the returns of the three months at *all* Welsh stations and compute the percentages. By discussing these in various ways, I concluded that the percentage rose 1 per cent. for each four inches of rain; we have seen that with an average of nine inches in the three months the percentage may be taken at 29; if then the average is 19 inches instead of 9 inches, 31½ per cent. should be taken. On the whole, I think that 31 per cent. (1 per cent. above Rhayader) is the most probable value, and that the range of error is nearly 3 per cent. +or—.

The underlined figures on the map have been computed with the value Oct.–Dec. 1866 = 31 per cent. of true mean annual fall, as shown in the following table:

Station.	Oct.—Dec. 1866.	True mean.
	Inches.	Inches.
Valley S.W. of Llanidloes	15·00	48·39
Hills above „	24·90	80·32
Valley at Carno	12·50	40·32
Hills near Canoffice	18·33	59·13
Valley at Llanwddyn	16·33	52·68
Hills above „	24·80	80·00

The mean of these values is 60 inches, if they had been computed with the value Oct.–Dec., = 28 per cent., the mean would have been 67 inches, and if with Oct.–Dec., = 34 per cent., 55 inches, so great is the uncertainty arising from the absence of old established stations.

The accuracy of adopting 31 per cent. is incidentally established by its making Mr. Bateman's valley gauge at Llanidloes indicate the same as the gauge established there in 1864.

In determining the probable average rainfall over the whole district, careful study of the map is necessary so as to determine, as nearly as may be, the areas to which the above quoted values apply. It will be seen that the returns are naturally divisible into two portions or groups, four stations having means between 40 and 60 inches, and two (at the back of Plynlimmon and Aran Mowddy respectively) 80 inches each; of course if we took the arithmetical mean it would imply that one-third of the district had a mean rainfall of 80 inches, which I cannot conceive to be possible, especially looking to other and wetter parts of Wales. I consider that these high values apply only to one-fifth or one-sixth of the whole district; this would give the mean rainfall for the entire area as 56 or 55 inches.

In conclusion I have to report—

(1.) *That although there are places in the vicinity of Snowdon with a mean rainfall exceeding* 110 *inches, no such falls are shown to exist in other parts of Wales.*

(2.) *That the old-established gauges surrounding the district in question have a mean annual rainfall of* 47 *inches.*

(3.) *That the new short period gauges apparently indicate a mean rainfall in the district of* 55 *or* 56 *inches, but that this value is uncertain to probably four inches plus or minus.*

(4.) *Therefore (subject to the before-mentioned uncertainty) the mean fall in three successive dry years would be* 44 *or* 45 *inches, and in one year of extreme drought the fall would only be* 36 *or* 37 *inches.*

G. J. SYMONS, F.M.S.

136, Camden Road, N.W.

G. J. Symons, Esq.
10 April 1867.

2730. (*Mr. Harrison.*) Are you at all aware of the circumstances under which the particular points of those rain gauges were fixed in the Cumberland district?—I fixed them myself, and I chose them as being, as near as I could make them, a fair geographical representation, that is to say, they were not picked out as wet places; I believe that it would be quite possible to pick out considerably wetter places if the attempt were systematically made with that object.

2731. In some evidence which has been given before us it was rather stated that the gauges had been moved from time to time, and some of them were placed with the view of ascertaining the greatest amount of rainfall?—That is really untrue, because they have never been moved at all; I put them down myself, and to the best of my belief they have never been touched from that time to this; the returns have all come up to me from the persons in charge of them, and who did not know whether the object was to get a larger amount of rain or a smaller amount of rain.

2732. That was stated, I believe, with regard to Dr. Miller's gauges?—One or two were moved, but only one or two. I think the gauge at Wastdale Head was moved; that was in 1845 or 1846; that certainly was moved about 200 yards or a second one was put up about 200 yards from the former one; but I am not aware of any moving or anything of that sort having been done with the view of increasing the return of the amount of rainfall.

2733. (*Col. Harness.*) Do you know whether it was an object with Dr. Miller to try to ascertain the maximum rainfall?—Yes; but he gained that as a rule not by moving the old gauges but by putting up new ones.

2734. Still some of the gauges, as appears from his records, were placed with that object?—Yes in the case of Seathwaite and the Borrowdale Valley; in fact up to this very year, one of my correspondents, a Mr. Fletcher, a relative of the late Dr. Miller, has moved a gauge from Mosedale to close to the Stye with the view of seeing whether he could get more water reported than in the case of the Stye, but he has not succeeded in doing so. In my own case I put those gauges so as to take in the whole of the district, and it will be seen that some of them do not give nearly so high an amount as other old established gauges.

2735. To what area do you suppose that the great rainfall of the Stye applies?—The Stye itself does not probably apply to more than three or four square miles, but that is not at all taken into the calculations upon which I have based the average of 77 inches in that district. The Stye gaugings I cut out of that, because the existing proposal cannot take them in; the levels are such that they cannot take in that district, and therefore of course the rainfall is also excluded. I do not know that I have any remark to add to the report; the Commissioners will see from the map which I have handed in that up in the neighbourhood of Snowden, there really is a heavy rainfall of 111 inches, but no such falls exist in other parts of Wales. [See (1), page 12].

2736. (*Sir J. Thwaites.*) Is your summit upon the high or the southern slope up beyond Bedgellert?—Bedgellert was one of the wettest places in Wales, and this is still further up the same valley. It is rather singular that in the first place the wettest part in Wales is 111 inches, that is two-thirds of the wettest in Cumberland, which is 160 at the Stye, and also the returns which we get now for this Welsh district are about two-thirds of what we got from Cumberland, and that was just a suggestion that I threw out almost at haphazard. I thought it was about that, and the result of careful inquiry is to corroborate it.

The witness withdrew.

Adjourned to Wednesday, the 8th of May, at half-past 11 o'clock.

Wednesday, 8th May 1867.

PRESENT:

HIS GRACE THE DUKE OF RICHMOND, K.G., IN THE CHAIR.

Sir JOHN THWAITES.	Colonel HARNESS.
Alderman Sir BENJAMIN PHILLIPS.	THOMAS ELLIOT HARRISON, Esq.

JOSEPH PRESTWICH, Esq.

J. Simon, Esq.
8 May 1867.

JOHN SIMON, Esq., examined.

2737. (*Chairman.*) You are a Fellow of the Royal Society are you not?—I am.

2738. And late Officer of Health to the City of London?—Yes.

2739. Will you state what your present position is?—I am medical officer to the Privy Council, and surgeon to St. Thomas's Hospital.

2740. You have no doubt given great consideration, have you not, to the subject of the supply of water to the metropolis, both in point of health, of comfort, and of cleanliness?—Yes, I have.

2741. Are you of opinion that the supply of water to the city of London is now as much as it ought to be?—I have not the quantity of that supply at this moment in my recollection. I dare say that the quantity pumped into the city, divided by the number of the population, may represent a sufficient supply per head, but of this quantity a large proportion runs to waste.

2742. (*Sir J. Thwaites.*) Do you mean the night population or the day population?—The permanent population taken from the census. I suppose that the use of water by the non-resident population of clerks, merchants, and so forth, is relatively but small.

2743. (*Chairman.*) Are you of opinion that the actual population of London, speaking more especially of the poorer classes, have not a sufficient supply?—I believe that the supply to the poorer parts of the population is, practically speaking, very far from sufficient, but that this depends rather on circumstances attaching to the intermittent manner of supply, than on scantiness of the quantity which the companies have at their disposal. Probably the state of things often resembles more or less that which I described in the City of London 18 years ago, when I first reported there on the subject. I then spoke of the supply as being, for masses of the population, in a practical sense, grossly insufficient. My language was then as follows:—"Thousands of the "population have no supply of it to the houses "where they dwell. For the possession of this first "necessary of social life such persons wholly depend "on their power of attending at some fixed hour of "the day, pail in hand, beside the nearest standcock, "where, with their neighbours, they wait their turn, "sometimes not without a struggle, during the "tedious dribbling of a single small pipe. Some-"times there is a partial improvement on this plan; "a group of houses will have a butt or cistern for "the common use of some scores of inmates, who "thus are saved the necessity of waiting at a stand-"cock, but who still remain most insufficiently supplied

J. Simon, Esq.
8 May 1867.

" with water. Next in the scale of improvement we " find water-pipes laid on to the houses, but the water " is turned on only for a few hours in the week, so " that all who care to be adequately supplied with it " must be provided with very spacious receptacles. " Receptacles are sometimes provided, and, in these, " which are often of the most objectionable descrip- " tion, water is retained for the purposes of diet and " washing, during a period which varies from 24 to " 72 hours. One of the most important purposes of " a water supply seems almost wholly abandoned, " that, namely, of having a large quantity daily devoted " to cleanse and clear the house drains and sewers, " and, in many cases where a water-pipe has been " conducted from the waterbutt to the privy, the " arrangement is one which gives to the drainage " little advantage of water, while it communicates to " the water a well-marked flavour of drainage."

2744. Does that state of things exist still?—I no longer know intimately the state of the city of London. I have ceased to be the Officer of Health of the City now for the last 12 years. Improvements have taken place since 1849; indeed I know that during the following six years, while I was still in the City, great improvements took place.

2745. Do you consider the system of intermittent water supply to be a good or bad one?—A very bad one.

2746. What is the reason which induces you to consider it a bad one?—My opinions about it are substantially those which I expressed in 1849 and 1850, in the following passages of my reports then made. From report of 1849:—"I consider the system of " intermittent water supply to be radically bad, not " only because it is a system of stint in what ought to " be lavishly bestowed, but also because of the necessity " which it creates that large and extensive receptacles " should be provided, and because of the liability to " contamination incurred by water which has to be " retained often during a considerable period. In " inspecting the courts and alleys of the city, one " constantly sees butts for the reception of water, either " public, or in the open yards of the houses, or some- " times in their cellars, and these butts, dirty, mould- " dering, and coverless, receiving soot and all other " impurities from the air, absorbing stench from the " adjacent cesspool, inviting filth from insects, vermin, " sparrows, cats, and children, their contents often " augmented through a rain-water pipe by the wash- " ings of the roof, and every hour becoming fustier " and more offensive. Nothing can be less like what " water should be than the fluid obtained under such " circumstances, and one hardly knows whether " this arrangement can be considered preferable to " the precarious chance of scuffling or dawdling at a " standcock. It may be doubted, too, whether even " in a far better class of houses the tenants' water " supply can be pronounced good. The cisternage is " better, and all arrangements connected with it are " generally such as to protect it from the grosser im- " purities which defile the waterbutts of the poor, " but the long retention of water in leaden cisterns " impairs its fitness for drinking, and the quantity " which any modern cistern will contain is very " generally insufficient for the legitimate require- " ments of the house during the intervals of supply. " Everyone who is personally familiar with the " working of this system of intermittent supply can " testify to its inconvenience, and though its evils " press with immeasurably greater severity on the " poor than on the rich, yet the latter are by " no means without experience on the subject." From report of 1850:—"I may correct a fallacy " which is apt to prevail with respect to the abundance " of supply. I have no reason whatever to doubt " that a very liberal allowance of water is daily " pumped into the City, enough, or more than enough, " so far as I know, to fulfil all necessary purposes. " But those purposes are not fulfilled by it. A cer- " tain large figure is stated as representing the average " quantity daily driven through the mains of the City; " this quantity is divided by the number of residents " within your area, and the inference is drawn that " each individual inmate of the City has at his dis- " posal 25 gallons a day, or (after deduction for public " purposes and the like) 21¼ for his domestic supply. " As an arithmetical conclusion from the premises " this may be true; nothing can be less accurate " as a practical representation of the facts. An ave- " rage amount of 3,000,000 gallons per diem may, or " may not, be pumped through the mains of the city, " but to calculate the available water supply from this " dividend, without previous deduction for the im- " mense escape of unavailable water by waste-pipes, or " otherwise, gives a most fictitious result. The large " waste which naturally arises in the system of inter- " mittent supply, has been well illustrated by some " evidence given by Mr. Lovick, before the late Metro- " politan Commission of Sewers, in respect of a par- " ticular block of nearly 1,200 houses.* Some of " the houses were of the higher, and many of the " poorer class, but the average might be stated to " be of the middle class, and to present a fair ex- " ample of an urban population. The drainage of " all these houses was discharged through one main " sewer. The run of water through this sewer was " carefully watched and gauged every hour, during the " night as well as the day, on days when the water " was on, that is to say, when the intermittent sup- " plies were delivered, and also on the ordinary days, " when the consumption of the houses was from butts " and cisterns, into which the intermittent supplies " were delivered. The gaugings of the discharge " of waste water into the sewer were checked by " gaugings of the consumption of water from the " butts and cisterns, during the interval of the delivery " of the supply by the Company. It was ascertained " that the average quantity discharged per diem " through the sewers was 44½ gallons per house; " but it appeared that on the days when the inter- " mittent supplies of water were on, the quantity " discharged per diem was 209 gallons per house. " The water in this district from defects in house " apparatus of distribution, incident to an inter- " mittent supply of water, was, on the water days, " 3¾ times greater than the consumption on " those days. No similar gaugings have, I believe, " been made within the city; so I am unable to tell " you with accuracy what are the proportions of " waste and consumption. In an interview with " your Committee on Health, when they were collec- " ting information on the subject, Mr. Mylne, the " engineer of the New River Company stated (as a " reason against fulfilling some object desired by the " Committee) that within the city of London, in con- " nection with its distributing apparatus, there existed " for the escape and waste of water, during the period " of supply, 'at least 10,000 open cocks.' Assuming " the accuracy of this statement, I doubt whether the " average available supply of water for domestic " purposes within the City can possibly exceed a " quarter of its alleged quantity; and I am persuaded " that there must be large numbers of persons to " whom the enjoyment even of that reduced average " is entirely unknown . . . . . On the extreme in- " convenience which attends the storage of water in " the poorer habitations of the City, I have already " reported to you, and will now only add that in- " creased experience has given much confirmation to " my view. Their receptacles are generally such as " contribute to the contamination of water, and are " constantly so arranged as to invite an admixture " of the most varied impurities. In the large " proportion of them, which are open casks, one " sees habitually a film of soot floating on the sur- " face; one sees (if indeed one can see so deeply " into water which is often turbid and opaque) " that filth and rubbish lie at the bottom; one sees the " interior of the cask itself dirty and mouldering. I " now merely glance at this part of the subject, because

* General Board of Health report on supply of water to the metropolis, page 120.

" you have already on other occasions allowed me to " state my knowledge at greater length. But there is " one evil in particular to which I would beg leave to " advert. Those works of drainage which are esta- " blished under your orders depend for their efficiency " on a proper supply of water; and in every case " where you enforce the construction of house drains, " you order that those drains shall be served efficiently " with water. Your wishes on this subject are nomi- " nally complied with by those on whom your orders " are served, but are often virtually evaded by a filthy " and ineffectual contrivance. The butt or cistern of " the house, that on which the inmates depend for " their supply of fresh and pure drinking water is " placed in immediate contiguity to the privy, so as " to reduce the requisite length of connecting pipe to " the fewest possible number of inches; the applica- " tion of water is not made discretionary on the users " of the privy, nor are any of the cheap and common " self-acting contrivances introduced; but the waste- " pipe of the butt or cistern is conducted into the dis- " charge pipe of the privy, so that, periodically, with " a frequency varying according to the arrangements " of the water company, the arrears of excrement are " removed, so far as the overflow of the water recep- " tacle may have power to dislodge and propel them. " Frequent evidence has been before me of the insuf- " ficiency of this arrangement, and, in addition to its " actual failure (on the reasons of which your surveyor " can speak more competently than I) there is strong " reason to object to its prevalence on other grounds. " Water, as you probably know, is a very active ab- " sorbent of many gaseous materials, and the open " butts, which are thus placed in immediate contact " and communication with privies, must rapidly be- " come infected by their foulness. I need not explain " to you how injurious an addition this is to the other " objectionable incidents of water-storage, or how un- " attractive as a beverage to the poor inhabitants of " the City must be this vapid, privy-flavoured stuff."

2747. Are you now speaking of London as a whole, or merely what is called the City of London?—When I speak of what I conceive to be the evils of the intermittent supply, I speak generally of it whether in the City or in London entirely, or in any other place. I look upon the intermittent supply as one which ought, if possible, to be got rid of.

2748. The long retention of water in leaden cisterns would render it unfit for drinking, would it not?—The long retention of water in any receptacles would make it disagreeable to drink.

2749. What is your opinion with regard to its being wholesome or unwholesome?—Hardish waters do not, I believe, under ordinary circumstances, derive much (if any) injurious impregnation from leaden cisterns, but it is undesirable, I think, that leaden cisterns should be in general use.

2750. You made use of the word "disagreeable" in your previous answer, and you say that water retained in any receptacle for a long time becomes disagreeable for drinking, which one can quite understand, but is it also unwholesome from that long retention?—Your Grace's question had reference to leaden cisterns, but waiving the question of what the nature of the cistern is, and looking only to the question of retention, water, so far as I know, does not thus become directly unwholesome; but I think it a great indirect unwholesomeness that water should be unacceptable to people, that the water of a great city should not be a nice water and pleasant to drink.

2751. You of course have analysed, and you are well acquainted with the quality of the London water?—Yes.

2752. What is your opinion as to its character?—Judging by chemical analyses, performed on it in what I may call its normal state, I am not aware that there is much fault to be found with it.

2753. You are speaking now of all the water supplied by the various companies?—Yes, speaking quite generally. Speaking of it in its broad ordinary chemical characters, as it would be reported on from a chemical laboratory, I should say it is a fair water supply.

2754. (*Sir B. Phillips.*) Are you now speaking of the whole supply of the metropolis?—Yes, speaking generally of it. But what I thus say of its average chemical constitution in its normal state does not touch the question of the water's liability to accidental very dangerous pollutions. There are dangerous qualities of water supply, with regard to which so far as I know (but I do not speak as a skilled chemist) chemists are totally unable to measure, even to demonstrate, the fatal influence that a water may have. A water may be, for instance, capable of spreading cholera, but chemists be unable to identify the particular contamination which produces that effect.

2755. (*Chairman.*) Have you any idea of the outbreak of cholera in any part of London having been caused by the quality of the water?—It is, I think, a matter of absolute demonstration that in the old epidemics, when the south side of London suffered so dreadfully from cholera, the great cause of the immense mortality there was the badness of the water supply then distributed to those districts of London.

2756. You mean the badness of the quality of the water?—Yes. In the interval between the 1849 epidemic and the 1854 epidemic, one of the two companies which supply the south side of London had amended its source of supply; it had gone higher up the river; and we at once lost a great part of the mortality on that side of the river. I may refer on this subject to a special report which I made in 1856 to the then General Board of Health, and which was laid before Parliament, on the last two cholera epidemics of London as affected by the consumption of impure water. I have just said that in 1853–4, after the one company had improved the quality of its supply, the southern district of London showed a greatly diminished liability to cholera. But it was found that this great difference did not prevail uniformly through the south side of London, but was confined to those houses which were supplied by the improved water supply. There was still great mortality on the south side of the river, but this belonged exclusively to the houses which were still supplied with impure water. The details of this gigantic crucial experiment, performed on half a million of people, are given in the report to which I have referred; this table, extracted from it, gives a striking synopsis of the results.

Death rates per 1,000 of living population in two epidemic periods.		In houses enumerated in 1854 as receiving their water supply.	
		From the Lambeth Company.	From the Southwark and Vauxhall Company.
Cholera	1848–9	12·5	11·8
	1853–4	3·7	13·0
Diarrhœa	1848–9	2·9	2·7
	1853–4	2·1	3·3

N.B.—Between the two epidemic periods the Lambeth Water Company had changed its source of supply.

Now we come to another epidemic period. And now fortunately both the companies which supply the south side of London, have ceased to give foul water. Subject to some qualifications which I will state presently, they both give fairly good water, and now, in consequence, the cholera mortality in those parts of London has been, comparatively speaking, insignificant. But, as is now matter of notoriety, within the area of another water company in London, the population last year suffered very dreadfully from cholera. I

J. Simon, Esq.

8 May 1867.

refer to certain eastern parts of London. Cholera in high development was confined to those parts of London, and those parts of London were in the area of one water company. And what makes this case the more remarkable is, that not the whole area of that water company suffered; the water company gave two waters, and the high cholera mortality was apparently restricted to those parts of London which received one of these two supplies.

2757. Which company was that?—It was the East London Company.

2758. (*Sir J. Thwaites.*) You stated that that company supplied two waters, and the black map (as you would call it) extended to that district supplied by one of those waters?—Yes, so to speak, to half the district of the East London Water Company. The source from which the company supplied this half of its district, was a source peculiarly exposed to contamination from a foul part of the river Lea.

2759. What was the nature of the contamination?—Sewage.

2760. And wherever that water was supplied there the cholera followed, did it not?—Speaking broadly for the whole metropolis, the area of intense cholera in 1866 was almost exactly the area of this particular water supply; nearly, if not absolutely, filling it; and scarcely, if at all, reaching beyond it.

2761. And there was a distinct line between the progress of the cholera, as marked by the supply of a superior water?—Generally speaking, yes. I lay two maps before the Commission which have been prepared for the Medical Department of the Privy Council Office, by Mr. Radcliffe, who has very elaborately investigated this epidemic. The maps (which will be published in my present annual report) sufficiently explain themselves.

2762. That impure water which you refer to was taken from the Lea?—Yes.

2763. (*Col. Harness.*) Do you also mean us to understand that a water might be productive of cholera, although it contained nothing which would be detectable by chemists?—Yes, I said something to that effect. A chemist would perhaps report that the water contained "organic matter," but "organic matter" covers an infinite variety of things, and he would have no means that I know for discriminating the organic matter which is really the ferment, the infectious material, of cholera, from a great number of other organic matters.

2764. He would distinguish the sewage organic matter from some other organic matters, would he not?—I am not quite sure of that.

2765. (*Sir J. Thwaites.*) When you speak of cisterns, you are of opinion, are you not, that lead should, as a principle, be avoided?—I think it very desirable that it should be avoided.

2766. But if water is of a certain degree of hardness, the mischief from lead would not be so great as if it were soft water?—Certainly not.

2767. When you speak of receptacles, and that water retained in them, although it might not be pleasant, would not seriously affect the health of the people, allow me to ask you this question: Having had great experience in the habitations of the poor, and the mode in which water is stored in filthy vessels often placed near to ashpits and privies, and other places where gases are generated, in your opinion, would not the tendency be that the water would absorb those gases and produce a zymotic effect upon those who used it?—Yes; but an answer to that is, of course, that the places ought not to have those stinks about them.

2768. We are now speaking of the constant as compared with the intermittent system of supply. Under the constant supply you would get rid of all those receptacles?—Yes.

2769. But under the intermittent system you must have the means of storage?—Yes.

2770. Have you a strong opinion upon that subject, that the water so retained in all probability would absorb gases which would be prejudicial to human health?—I have a very strong opinion that the water might absorb matters which would endanger health.

2771. (*Chairman.*) You are distinctly of opinion that it should be a constant supply as opposed to an intermittent supply?—I am strongly of that opinion.

2772. (*Sir J. Thwaites.*) You mean that the supply should be on the same system as at Philadelphia, New York, Nottingham, Preston, Glasgow, Newcastle, and Bristol?—Yes.

2773. In all those towns the constant system is, I believe, in operation?—I believe so.

2774. Have you heard of any difficulty that either of those towns has expressed in the application of the constant supply as compared with the intermittent?—I have understood that certain strict regulations are necessary, as between the water company and its customers, where the constant supply is given. And although I have not lately gone over the evidence on the subject, I am aware that the water companies allege great difficulties in giving a constant supply. I do not pretend to judge of the engineering part of the question; I speak only as to the desideratum for health. It is in the highest degree a desideratum for health that the supply be constant.

2775. Speaking generally, you are of opinion that the water would be in a better condition for the general health of the people under the system of a constant supply rather than of an intermittent supply, even disregarding the mechanical arrangements for storage?—Yes.

2776. You prefer taking it out of the pipes direct rather than having it stored in cisterns, whether properly constructed or ill constructed?—Yes, even assuming a good storage, still it would be better that it should be constant.

2777. Has your attention been directed to the quality of the water in London for drinking purposes, as to the effect upon the health of the inhabitants, as compared with water of a softer and purer character?—I have no evidence upon that subject. I think that, practically, the only very important sanitary question as regards the quality of the water supply to London is the question of organic admixture. I do not think that the question of a few grains of lime in a gallon of water can be regarded as a very important sanitary question.

2778. Then, in your judgment, the presence of lime, or two or three degrees of hardness in the water, would not be a matter of much consideration, supposing the water were free from organic impurities?—Quite so, as regards the public health.

2779. For drinking purposes, probably a little hardness in the water would add to its life and pleasantness to the taste?—I would not quite say that. I have found soft waters, or, at all events, hard water artificially softened, very agreeable.

2780. (*Chairman.*) Is it the case that when hard water is boiled it loses its hardness and becomes soft; I mean for washing purposes?—With some hard waters that is the case.

2781. Is that so with the London waters?—Yes, to a great extent.

2782. It has been stated in evidence that one of the great advantages of soft water, such as would be brought from Wales or the lakes of Cumberland, would be great economy in the use of soap in washing, do you agree with that?—I believe there is no doubt of that.

2783. We are told that soft water requires very little soap to get a very large quantity of lather, and also that a hard water when boiled becomes soft, but if when a hard water is boiled it becomes soft, is there much difference in the merits of the two waters; does the proportion between them still remain, with regard to the use of soap?—The soft water then stands in the same relation to the soap as if it had been originally soft, or comparatively soft; that is to say, its demerits in relation to soap are reduced, so far as the softening process extends.

2784. Both the hard water and the soft water being boiled, would you require less soap in the use of

the boiled soft water than you would in the use of the boiled hard water?—If by "soft" water you mean absolutely limeless water, such water cannot become softer by boiling, but on the other hand no amount of boiling, I believe, can quite perfectly soften the hard waters on which it is most effectual.

2785. (*Mr. Harrison.*) The system of putting quicklime into the water would reduce the hardness, would it not?—Yes. And it must not be lost sight of that that process of softening hard water in boiling is grievously at the expense of our apparatus; it furs our boilers, and gives a good deal of trouble in other ways.

2786. (*Chairman.*) Therefore that would be an answer, that a soft water boiled is better than a hard water boiled, although the hard water may become to a certain extent soft?—Yes.

2787. (*Mr. Harrison.*) And there would be the cost of the fuel to reduce it to soft?—Yes.

2788. (*Col. Harness.*) A water taken from chalk deposits the chalk in boiling, does it deposit it all?—I apprehend not.

2789. It is still a hard water?—Yes, as compared with distilled water or with a first-rate mountain water, such as some of the soft supplies which have been spoken of.

2790. (*Sir J. Thwaites.*) Speaking generally, if you had the choice of soft water compared with water of seven or eight degrees of hardness you would elect the soft water for general manufacturing and drinking purposes?—As regards many manufacturing uses, I believe it to be commonly conceded that soft water has very great advantages. As regards drinking purposes, I am not sure of any important difference, but am inclined to prefer the soft water.

2791. (*Mr. Prestwich.*) Do you know of any experiments which have been made with regard to the use of soft water and hard water upon health?—If by hard water is meant such water as we have in London, I am not aware of any facts of the smallest value showing difference of effect between such water and soft water.

2792. It has been stated that there are certain classes of diseases more prevalent in districts where hard water is used than in others, for example, diseases of the bladder and the stone; can you give us any evidence on that point?—I do not think there is any evidence that is worth a rush upon that subject.

2793. That evidence which was given by Dr. Prout some years ago, you do not attach much importance to?—I do not remember the exact language of Dr. Prout upon the subject, nor know whether he professed to argue from any large field of observation; but I believe that no statistics of value exist in proof of such an assertion.

2794. (*Chairman.*) Is it true that diseases of the bladder prevail very much in Norfolk?—It has been said so, and of course there have been many explanations, among which Norfolk dumplings hold a chief place; but when that assertion became current, Norwich had a famous lithotomist. It is possible that his reputation, by attracting sufferers into temporary residence in the district, or perhaps his zeal in discovering cases of stone, may have given the district a fictitiously lithogenous character.

2795. (*Sir J. Thwaites.*) Has your attention been directed at all to the system of filtration of the Thames water?—It has been generally directed to it, but I cannot say that I have recently tested the results; I have not confidence in the sufficiency of the filtration to a degree that would, if I may quote my own case, lead me to dispense with having a charcoal filter in my own house; I draw all my water through a charcoal filter.

2796. I presume that the filtration adopted by the water companies would simply take out that which is held in mechanical suspension, but all that is held in solution must pass through unaffected?—When a filter is fresh and clean, it would effect also some amount of chemical conversion of the dissolved matter, but filtration, as enforced on water companies, ought not, I suspect, to be relied upon for the separation of anything beyond gross mechanical impurities.

2797. Not so much as if the water passed through charcoal?—No, certainly not.

2798. (*Mr. Prestwich.*) Are you aware that any experiments have been made at St. Thomas's Hospital or at any public establishment with regard to the quantity of water required per head in such establishments apart from waste?—I am not prepared to quote any observations of that kind, but I observe that in my City Reports to which I have already referred, I said the average of requirement for the general population might in my opinion reasonably be estimated at about 12 gallons per person per diem.

2799. Have you seen any cause to alter that estimate?—I have never since had occasion to go into the subject as thoroughly as I went into it then. I then took a great deal of pains with it, and got what evidence I could about it, of which I only submitted the general result. The estimate there given is the best that I could then form. Probably there are better means now than existed then of judging in the matter.

2800. Would that estimate refer to the wants of the individual, or does it take the average including the quantity used for public supply?—It was exclusive of what was wanted for public supply.

2801. Including the public supply what should you consider the quantity required per head of the population for all purposes?—I have no special means of judging what quantities would be wanted for sewers and street-watering and fires.

2802. (*Chairman.*) It has been variously stated between 25 and 50 gallons?—I hardly know what means there are of estimating it per head, except the actual supply of the companies. The great quantity of waste which there is in the present supply makes the conclusions uncertain. There must be an enormous waste.

2803. You think that a constant service supply without those pumps and standcocks and so forth would lead to a very much more economical use of water?—I think so.

2804. (*Sir B. Phillips.*) Did I understand you correctly in the earlier part of your examination to say that you considered the quantity of water supplied to London to be good?—Yes, fairly good, if considered apart from the question—which I reserve as quite a special one—of organic admixture.

2805. You mean that the water itself is good?—Yes, I think it in its natural state to be fairly good.

2806. You have also stated that that did not exhaust the question, because if I understood you rightly there might be particles in the water which no chemist could discover and which might tend to produce certain diseases?—That is so.

2807. I apprehend that that observation (I am now asking of course what may be a scientific question) does not only refer to the water supply of London, but the same observation would refer to any other water from any other source?—Undoubtedly, and yet I think that perhaps you are a little misunderstanding what I mean. I mean that the question of good supply or bad supply is not to be judged only by what the chemists from their laboratory can tell you of the water. The greater part of the water supply to London, as you are aware, is pumped from the Thames. That portion is taken from the Thames after a million of population has drained into the river. Nothing which chemists in the present state of their science can report (negatively) as to their findings in London water will alter the fact of that filthy admixture. And I know that that fact represents a certain amount of danger to the population that receives the water.

2808. Then that danger is not discoverable by chemists?—I do not know that chemists could have discovered the infectious quality which is believed to have existed in the East London water supply in the beginning of last July. I do not know that chemists could have identified it, or could have come down

J. Simon, Esq.

8 May 1867.

upon it as they would come down upon arsenic or copper.

2809. Then if it could not be discovered you only presume that it might be so?—We trace the sewage into the water, we trace the water into the district, and we trace the inhabitant to his cholera and death.

2810. (*Mr. Prestwich.*) I think you mean to say that although you detect in this water the presence of organic matter, you cannot detect whether this organic matter is or is not of a more or less poisonous quality; that is to say, whether it bears the germs of any particular disease?—Quite so.

2811. Would not the presence of organic matter in water give rise to suspicion?—Yes.

2812. But you have not been able in all those cases of suspicion to trace the cause of the evil which has arisen from the use of those waters?—There are certain organic matters in water, peaty matters for instance, as to which I do not know of my own knowledge that they do any harm. I think it would be safer that water should be without any organic mixture, but with regard to some of those matters we do not know that they do harm. The water which has done very great harm in London on various occasions, as we believe, has been water conveying what by a figure of speech I may call the actual seeds of specific disease. Chemists cannot identify those seeds. Whether microscopists can, is a question which is likely, within the course of the next 12 months, to be settled: at the present moment there is a belief amongst some very competent persons that such water would contain demonstrable microscopical organic germs, each carrying an infectious power. My practical point is, that what one has to do is not to take water out of a reservoir or out of a tap and give it to a chemist and say, Tell me is this wholesome water. What one has to do is to guard the supply with the utmost strictness against every foul admixture. It ought to be made an absolute condition for a public water supply, that it should be incontaminable by drainage.

2813. (*Chairman.*) Then whatever appearance the water had when it arrived at a house, if you knew that it had been contaminated before it was taken into the pipes of the company, you would assume that that water was bad?—Yes.

2814. (*Sir B. Phillips.*) Do not you think that the main drainage is likely to rid us of a great deal of the river impurities?—The main drainage will do a great deal for us, but you will observe that our water supply, for a great part of London, is drawn above Teddington lock, and the main drainage of London, would not, of course, do anything for that. Above that point a million of population drains into the river.

2815. (*Mr. Harrison.*) Are you aware of the Act passed last session giving power to the Commissioners of the river Thames to compel all the towns on its bank to do away with the discharge of their sewage into the Thames?—Yes, it is a most important power, and I hope it will be vigorously exercised.

2816. Are you aware also with regard to the river Lee, that a report was presented to the House of Commons within this week from the Rivers Pollution Commissioners, who have recommended the same course with regard to the Lea; namely, absolute compulsion as to all the towns taking their drainage away from the Lea?—I have not seen that report, but I knew that such a one was about to be made.

2817. But assuming that the power given to the Commissioners of the River Thames conservancy are fully carried out, which amount to an absolute prohibition as to the towns drawing their sewage directly into the Thames, would not that, in your opinion, be an immense advantage in purifying the present supply of London which is taken now above Teddington lock?—Yes, it would be a very great gain.

2818. Supposing that the prohibition were extended to all sewage going directly into the river at any part of it, and that under the powers which are given to the Thames Conservancy Board, they compelled the towns to distribute their sewage for the purposes of irrigating the land, and consequently that all the water falling on the surface merely came into the river after having passed through the soil, do you think that in that case the Thames water taken above Teddington lock would still be polluted, or should you consider it to be practically free from pollution?—Assuming a sufficient thickness of soil, I should so consider it.

2819. Can you form any opinion at all in that case as to whether the water taken above Teddington lock would still be impure and unwholesome supposing, for instance, it had travelled exposed to the atmosphere for 15 or 20 miles of river?—I should think it quite a safe water as regards the danger that we are speaking of.

2820. Supposing that Parliament adopted the recommendation which I know to be the result of the inquiry on the river Lea, by which all the towns upon that river should be compelled, upon the same principle as they will be on the Thames, to keep their sewage entirely free from the river, would you not then consider that, as far as the Lea is concerned, the water coming chiefly as it does from the chalk would be a good and wholesome water for the supply of London?—Yes, very good; but the dreadful mischief which is believed to have resulted from the badness of the Lea supply last year is not, so far as I know the facts, attributed to water derived directly from the company's avowed sources in the river Lea, but is attributed to the reservoirs having to some extent received water from a part of the Lea which is not avowed as a source of supply, and is in fact the common sewer of a large mass of metropolitan and suburban population. The avowed sources of the company's supply are high up the Lea, where the impurities are, comparatively speaking, scanty; but the Old Ford reservoirs of the company adjoin the river Lea in a part of its course where it is extremely foul. There were facilities for the passage of this foul water certainly into one set of reservoirs, and probably into another set of reservoirs, and it is believed to have been this admixture of foul water, which conveyed the seeds of cholera into the supply.

2821. (*Sir J. Thwaites.*) Do you mean from one of those stagnant cuts in that neighbourhood?—Yes.

2822. (*Mr. Harrison.*) Taking generally the question of the large extent of the Thames, and taking the fact that the water beyond all question is first absorbed into the chalk and then flows out again into the Thames, you do not see that there is anything objectionable in the water of the Thames basin itself?—Apart from sewage admixture and pollutions certainly not, looking upon it in its natural state.

2823. Although it is a hard water, in some cases to even 18 or 20 degrees, yet that would not be in your mind, in a sanitary point of view, objectionable to use that water?—It would not make it unwholesome water, so far as I know, for drinking, but there would remain of course the economical question.

2824. Therefore we may assume that the question, as between the existing water in the Thames basin and pure soft water, would be practically reduced to its economical results for the purposes of washing and culinary purposes and domestic use?—Yes, and the question of a quantitative sufficiency; whether the Thames would give enough water.

2825. As far as the simple sanitary question goes, you see no objection at all to it?—No.

2826. Therefore it is reduced simply to the question of economy, as between the use of soft water and hard, assuming the sewage to be kept free from it?—I think so.

2827. With regard to the constant supply, there is a great difference of opinion as to whether it ought to be by cisterns, or whether the water should be taken directly from the pipes. Are you aware whether in the towns which you have mentioned, where the supply is constant, any uniform system has been adopted?—I am not able to speak off-hand upon that subject, it is long since I looked over that part of the question.

2828. Still, in all those cases where they have what

professes to be a constant supply, they are liable to the accidental bursting of pipes, and, occasionally, for some time to be without a supply?—Yes, but cisterns do not give security against accident.

2829. But your chief object would be by having the water direct from the pipes without cisterns to avoid any stagnation of water that might take place, and the accumulation of dirt or filth in those cisterns?—Yes, and to avoid, as regards the immense masses of the poorer population, the expensive necessity of storage.

2830. As I gather from your report, as regards the poorer parts of London you attribute even more importance to having a constant supply than the other part of the question?—Yes. It matters very little, of course, to people who have money and large houses whether they have cisterns or not, but to the poor it matters immensely. For many years I have had nothing to do with the details of those local administrations, but when I had to do with the city of London as officer of health, it struck me that almost the most important reform that was wanted in the sanitary circumstances of the poor was the substitution of the constant for the intermittent water supply.

2831. That you would look upon as really affecting the health of the poorer classes, perhaps, to a very much larger extent than their having an abundant supply of water both for cleanliness and washing their clothes, and every thing in connexion with it?—Yes.

2832. In the present state of London that is really one of the great deficiencies that they have to labour under in the poorer parts?—Yes. I cannot conceive of a person who knows the difference between decent water and other water drinking such stuff as would be drawn out of a butt in the city.

2833. Are you aware of any statistics that have been taken within the last year or two in the city of London, in any of the model lodging-houses and other places, as to the actual consumption of water where they have had an unlimited supply?—No, I cannot give information upon that point.

2834. Then taking the question of soft water, even taking the purest, which I suppose is that supplied to Manchester, can you give any idea at all as to the value which you attach to it as a pure question of economy as between soft water and hard water?—What little information upon that subject I have had has been derived from others. I have never made any local inquiry about it; but such information as I have derived, for instance from Mr. Bateman, would lead me to think that the saving is very great and very important.

2835. Having at your door a soft water or hard water, you would give a decided preference to soft water, taking all questions of economy and health into account?—An overwhelming preference with regard to economy; about that there can be no doubt. And as regards health my bias is in favour of soft water, but I cannot say that I think the case established against hard water (i.e. against hard water of such comparatively few degrees of chalk hardness or carbonate of lime hardness as you have in the London waters) that it acts injuriously on health. It is different, of course, when you come to certain other hardnesses of water; but I do not think that the hardness, for instance, of the New River Company's water can be considered detrimental to health.

2836. (*Chairman.*) What is that hardness measured by—degrees?—It was 16 last week in the Registrar-General's returns.

2837. (*Sir J. Thwaites.*) When you speak of the interception of sewage flowing into the Thames, and the general power of the Thames Conservancy Board to accomplish that object, the Thames itself would be a proper source of supply to the metropolis; but have you, apart from the question of sewage, considered the condition of the Thames basin as a gathering area, having regard to the high state of cultivation of the land and the use of manures, artificial and other, and the washing of water into the Thames, what the effect upon the water would be for domestic purposes?—The earth is a most powerful absorbent and disinfectant of the materials used as manure, and I do not think that practically any important danger would attach to the outflow from cultivated lands.

2838. (*Chairman.*) The sewage of towns, I conclude, is what you would fear most?—One would not wish in these matters to draw very minute distinctions: one would wish to keep all sorts of nastiness out of the water: but the tremendous danger to the population is the introduction of human sewage with the germs of contagious disease in it. It is of course an entirely new thing in the history of the world, this power that water companies have, to distribute the germs of disease in that way. One single water company distributes its supply to perhaps half a million, or more, of population. The danger is enormous if such a supply is drawn from sources near dense population, or sources in any other way contaminable by sewage. This power of life and death in commercial hands is something for which till recently there has been no precedent in the world, and even yet the public seems but slightly awake to its importance.

2839. (*Sir J. Thwaites.*) Supposing that those upper towns are driven to deodorise their sewage, or to apply it for irrigation to the land, would the water that must pass off ultimately into the river be sufficiently purified, do you think, so as not to affect the river prejudicially?—A speculative answer is not worth much upon this subject, and I can only give a speculative answer at present. I think it very likely that the water would be harmless, but possibly the result might show that the water could not be deemed quite safe.

2840. Have you examined the water at Croydon as it passes into the Wandle by a culvert after the sewage has been applied to the land; have you observed that it is perfectly clear and colourless, and yet it holds in solution a vast amount of deleterious qualities?—I have not examined it, but in a report which I have recently received on the subject the following statement is contained: "At Beddington, 1,000,000 "gallons a day have now been employed for some "years to irrigate 310 acres of land. There are no "complaints of injury to the neighbourhood, and the "agricultural value of the land has much increased, "the sewage being productive of equally good results "in dry and in wet weather. The sewage, after "passing over the land, contains just one grain of "total impurity more than the water of the Croydon "Waterworks—22 and 23 grains to the gallon; here "the soil is porous gravel. At a second outfall at "Thornton Heath, 250,000 gallons daily are used on 20 "acres of land where grass and market produce are "grown, and for most crops it is found to give re-"markably favourable results; here again the soil is "gravel. At a third outfall in Beckenham parish 37 "acres of stiff clay soil are irrigated, and the largest "and healthiest crops of all to which the sewage is "applied are got from this clay soil, a circumstance "that was not expected, while the purity of the "effluent water is almost absolute." Speaking generally of places where land is manured, there can be no doubt whatever that, with a certain intensity of manuring and a certain smallness of area, the water at the outflow would be still loaded with putrescible organic matters; but whether the manuring in the Thames basin would be of that sort, whether it would be so intense in proportion to the area that the river water would be still putrescible, is, I think, doubtful. I should have thought not, but as I have said it is not a matter upon which a speculative opinion is worth anything. Of course the same conservation of the river as purports to provide against direct infusions of sewage ought to provide also against every influx of tainted land-drainage.

2841. (*Col. Harness.*) The nature of the soil through which it passed would affect it, would it not?—Yes, very much indeed.

J. Simon, Esq.
8 May 1867.

2842. (*Mr. Prestwich.*) And the nature of the flow of the river also?—Yes.

2843. In considering the question of constant supply, would not it be an important point that the water to be so delivered would be generally cooler and fresher water than that which is now delivered on the system of intermittent supply?—I look upon that as of very great importance indeed. I do not think it has been half enough considered how important it is that the water of a great city should be pleasant for drinking.

The witness withdrew.

Dr. W. Farr.

Dr. William Farr examined.

2844. (*Sir J. Thwaites.*) You are, I believe, a Fellow of the Royal Society and Superintendent of the Statistical Department of the General Register Office?—Yes.

2845. Has your attention been directed to the supply of water, and the quality of water and its effect upon the health of the people?—It has for many years.

2846. And especially within the metropolis?—Yes.

2847. Are you able to give the Commission any information as to the present supply, and how it affects the health of the metropolis?—With regard to the importance which I attach to the water supply, I made a representation to the Registrar-General after the cholera epidemics of 1849 and 1854, which led to his getting the waters of London analysed regularly by Dr. Robert Dundas Thompson in the first instance, and latterly by Professor Hofmann and Professor Frankland, of the Royal College of Chemistry.

2848. Since Professor Hofmann left England, have you had anyone associated with Dr. Frankland?—No; Dr. Frankland succeeded Professor Hofmann at the Royal College of Chemistry, and he naturally continued the analyses.

2849. Does he continue to make monthly analyses of the water?—Yes, and this is the one published to day (*handing in the same*).

2850. In this analysis of Dr. Frankland the Chelsea, West Middlesex, Southwark, Vauxhall, Grand Junction, Lambeth, Kent, New River, and East London waters appear to be contrasted with the Loch Katrine water?—Yes.

2851. Is that Loch Katrine water taken to be the standard water now?—We consider it to be one of the best standards, and remarks are made on it in the weekly return of to-day, which I will read to the Commission, "Loch Katrine water is an instance of the "purest water in actual use in a great city: in 100,000 "parts there are only three parts of extraneous stuff; "except this all is water. The London waters of "April contained according to Dr. Frankland's "analysis in 100,000 tons about 29 tons of extra- "neous matters of various kinds; the proportions "ranging from 26 tons in the New River water to "40 tons in the water supplied by the Kent Com- "pany." That is for determining merely the amount of extraneous matter. For testing the hardness, Dr. Frankland adopts the process suggested by Dr. Clark, on a different scale however, and he shows in the analysis of April last that the hardness varies from 16 degrees of hardness in the East London water to 21 degrees in the Kent Company's water, and the Thames Companies' water varies from about 16 to 18 degrees of hardness. Then Dr. Frankland has latterly extended the analysis so as to determine the amount of organic carbon as he calls it, and the amount of nitrogen in those waters.

2852. What does he mean by organic carbon?—Carbon which has recently existed in some organic body, either animal or vegetable. He finds that in the water and he compares it with the quantity that would be supplied by sewage of an average degree of dilution, estimated I think by Professor Way. He finds that the proportion of carbon and nitrogen was equivalent to that supplied by a quantity of sewage ranging from 1,945 to 3,155 tons in every 100,000 tons of water. It is therefore gratifying to learn that as far as chemistry can determine the original sewage contamination had been converted into comparatively innocuous inorganic compounds before its delivery to the consumers. It is Dr. Frankland's opinion that all those organic matters which probably would have been injurious if supplied directly to the population have undergone changes in the earth, in the rivers, and in the filters of the companies.

2853. What was the time occupied in producing that chemical change?—Dr. Frankland states here that he has taken those waters from the mains, and not from the butts. He finds that those substances existed in the water, but that they are changed into nitrates and nitrites and ammonia, and that they are no longer in a state of sewage.

2854. And therefore not injurious to human beings?—Not injurious to health.

2855. (*Mr. Harrison.*) That analysis refers to the month of April does it not?—Yes; I merely cite this to show the present system of analysis in operation.

2856. (*Col. Harness.*) He does not attempt to lead one to assume any period that has elapsed since it was in contamination with the sewage, but merely that it has at some period been in contact with sewage?—It contains the amount of those ingredients which would be supplied by those amounts of sewage at some time or other.

2857. (*Sir J. Thwaites.*) As I understand the result of the analysis made by Dr. Frankland is that he detects the presence of sewage broken up by a chemical change into other compounds, and that although in its concentrated form as sewage it would be injurious to the public health, yet now in its altered chemical condition it is not injurious to the public health?—That is so.

2858. What I want to know is whether Dr. Frankland's attention had been directed to the time occupied in the transformation of this sewage into the several elements referred to by him?—He does not mention that. Perhaps I have not stated quite correctly what Dr. Frankland says. He says that he finds those amounts of organic carbon and nitrogen in the London waters, and then to give us an idea of the original degree of impurity he says what amount of average sewage would produce that amount of nitrogen and carbon, and according to his estimate if 1,945 tons of sewage had been poured out at any time into the waters which the Southwark and Vauxhall Company supply, it would have given the result which he detects by chemical analysis on the 12th of April. He takes that water from Barclay's brewery on the 12th of April, he finds certain substances, nitrogen and other substances, the quantities of which he determines, and then he says that those quantities are equivalent to the quantities that would be produced by sewage of an average degree of impurity.

2859. Is there anything in Dr. Frankland's return to show that if sewage discharged into the river at point A is conveyed through a large volume of water some few miles down the river, becoming exposed to the atmosphere from time to time, as the effect of that exposure the sewage might become broken up into elements that would not be offensive, and, in point of fact, it would become deodorised and purified by the action of the atmosphere, so as to be rendered innocuous?—I would rather express my own opinions than attempt to express Dr. Frankland's, as I am not in possession of all his views.

2860. What is your opinion upon the subject?—This analysis is only taken once in the month, and we have found that the excellent use of it has been to keep the water companies on the alert, but it necessarily does not determine the variable quantity of impurity in the waters. It may happen, for instance, that on

April the 11th, the sewage, instead of being all converted into innocuous matters, might have been in a state so as to be injurious to health.

2861. But have you, in the interests of health, instituted any inquiry as to the chemical result of sewage poured into a river and being conveyed in the natural volume of that river some few miles and exposed to the atmosphere, so as to be able to speak to its condition at the end of the stream?—I have not done so; that, of course, is a purely chemical inquiry. There have been chemical analyses of the water, and it certainly does undergo transformations, but I apprehend that the eggs of worms or the seeds of disease in some way would often remain unchanged.

2862. (*Mr. Harrison.*) This is the point, I think, to which you refer in the report of Dr. Frankland: "By gradual oxidation, partly in the pores of the "soil, partly in the Thames or its tributaries, and "partly in the reservoirs, filters, and conduits of the "Chelsea Company, this sewage contamination has "been converted into comparatively innocuous, inor-"ganic compounds before its delivery to consumers." That is Dr. Frankland's report for the month of April. —Yes. I mean to state that it is my opinion that the quantity of those matters thrown into the river varies very much. It depends very much upon the floods and the rainfall, and so on. It is a fluctuating quantity, and it might, and it generally is, I believe, reduced into that innocuous form, but it might also be brought down in a form that would render it unsafe.

2863. (*Sir J. Thwaites.*) Rivers, of course, have a power of their own, and nature has a power of its own, to purify the water by exposure to the atmosphere, and the question which I put to you is, whether that power would operate so as to purify water that might be affected by the discharge of sewage into it?—I should not think it would invariably; it might frequently do so, but it would depend upon the quantity that was poured into the river, and also upon the temperature. The condition of the organic matter in the river will vary according to the temperature. As you will remember, the state of the Thames was very different when the temperature was high from what it was when the temperature was low.

2864. Do you recollect the experiments at Leicester, where the river became so impure from the discharge of sewage into it that for 3 or 4 miles the fish were destroyed, and plants also, but at the end of that fourth mile, I think, plants began to revive, and the fish also, and the stream assumed its natural condition?—I recollect something of that kind, but I could not state it as evidence of my own. However, I have no doubt that it is a general truth.

2865. Having regard, therefore, to the condition of the London waters, do you attribute the outbreak of cholera in the eastern division of the metropolis to the water supplied to those districts, or to any other cause? —The epidemic of cholera broke out in London, as you are aware, last year, about July. It had been prevailing in different countries in Europe, and happened to reach this country then. Of course my attention was directed to it. We watched its progress in London, and I have here a series of papers which I can put in, if the Commission would like to have them. They are extracted from the Registrar-General's weekly return, and contain all that he states on the progress of the epidemic. I would call the attention of the Commission particularly to the return of the week ending July 28th last year. Cases of disease had occurred in certain numbers in the beginning of July, but there was nothing decisive until July the 14th, when these remarks occur in the weekly table: "The intense heat "of the weather has favoured the development of "diarrhœal disorders. Diarrhœa was fatal in 150 "cases; and 32 deaths by cholera are recorded in the "week, of which 2 were in the west, 4 in the north, "3 in the central, 20 in the east, and 3 in the south "districts. About half of the number are cases of "death by choleraic diarrhœa, or summer cholera," and those cases are given. Then it says, "Immediate "measures should be adopted by house to house visi-"tation, and otherwise, to treat the disease in its "earliest stage of diarrhœa, and the cholera excre-"tions should be effectually removed or destroyed." We saw at once that there was likely to be an outbreak of the epidemic in London. The number in the next week increased from 32 to 346. "Of the 346 fatal "cases now recorded, 308 occurred in the east dis-"tricts of the metropolis." I will describe very briefly the state of things existing in the next week ending July the 28th. "The deaths registered in London "during the week were 2,600. The deaths in the "present return exceed by 1,213 the estimated num-"ber." That was quite alarming, and it was the first decisive display of the force of the epidemic. "The "excess of deaths is caused entirely by cholera "and diarrhœa; 904 deaths by cholera, 349 by "diarrhœa, were registered in the week, making "in the aggregate 1,253 deaths." We saw how they had run up from 6 to 14, 32, 346, and 904 by cholera. Then as to locality, "It is a pecu-"liarity of the case that a greater part of this "slaughter in seven days of 1,253 people of all ages "took place within a limited portion of the London "area. 924 of the deaths, 811 by cholera and 113 "by diarrhœa, were registered in the six districts of "Bethnal Green, Whitechapel, St. George's in the "East, Stepney, Mile End Old Town, and Poplar, "including Bow, among about a seventh part of the "population of London, and on one-fourteenth of its "area. The attack extends all along the north side "of the Thames from the river Lea and the Isle of "Dogs to the Tower of London; Limehouse Basin "and the Regent's Canal are the central line of the "attack, which stretches as far north as Victoria "Park. This is essentially the port of London, in-"habited by its maritime population. The canals "and the basin are full of foul water, and are appa-"rently connected with the Limehouse Cut, the "Hackney Cut, and the river Lea. The East London "Waterworks canal draws its supply from the river "at Lea Bridge, where there is a reservoir, and runs "for a couple of miles by the side of the Hackney "Cut down to its other reservoirs north of Bow and "near the Lea. The present cholera field derives its "waters from these works. It is right to add that "the water has hitherto borne a comparison with the "other London waters in Dr. Frankland's analyses. "To-day at Poplar the water looks clear, and no "complaints are made of its quality. The company "will no doubt take exemplary pains to filter its "waters; but it is not easy to guarantee the purity "of water drawn from such a river as the Lea, in "dangerous proximity to sewers, cuts, and canals."

2866. Did you observe any filtration from those cuts?—I went down to this district on the Monday before writing this report, and went round to a great number of the houses where the people were suffering, and I noticed the dangerous effect of the waterbutts there. Then the return goes on to say, "Whoever "will take the trouble to go among the people now "suffering in crowded dwellings, will see the danger "of the waterbutt; poor women are washing the "dirty linen of patients with water drawn from those "vessels, which are often found close to the water-"closets. It would be a source of additional safety "to London, if the tanks and butts were all abolished, "and the pipes were filled on the system of constant "supply. The time has come for this reform." We have all along been convinced of the importance of the constant supply, so as to get rid of those evils which are of course most felt in the houses of the poor, where they have not the conveniences that the rich enjoy. "The mortality is overwhelming in "some of the districts. In Poplar alone 145, in Bow "188 people died last week, including Dr. Ansell, "the meritorious health officer, and Mr. Ceeley, clerk "to the Board of Works, whose name figures on the "placards. The people are falling ill every hour; "you see them of all ages, children and adults, lying "about their beds like people under the influence of "a deadly poison, some acutely suffering, nearly all

r. W. Farr.
May 1867.

"conscious of their fate and of all that is going on around them. Here the doctor is drawn in by the husband to see the wife now attacked; there the husband lies in spasms; here is an old woman seated dead with eyes wide open; there lies a fine four-year old child, his curly head drooping in death, but his mother says the pulse is strong and he takes what she gives him; an older brother, just recovered, is running about. Several wards of the London hospitals are full of patients, many of them very young children in all stages of the disease; some dying, some well again and playing. The medical men have no rest, and with the health officers are nobly doing their duty; brave men ready to lay down their lives for their patients. The people themselves are most patient, most willing to help each other, the women always in front and none shrinking danger. There is no desertion of children, husbands, wives, fathers, or mothers, from fear. In the midst of this scene, the authorities have been to some extent paralysed. The nuisance inspectors are not sufficiently numerous, neither are the medical officers. The administrative work has not been organized with sufficient promptitude, and is not carried out with sufficient energy. Such a calamity as this may well call forth the whole resources of London, and what is especially wanted is executive power well organized in conjunction with the medical health officers. The people of East London want help." The Commission will see from that how we came to the conclusion that the great mortality of those particular districts was caused by the distribution of impure water. I will hand in a table, which I will ask the Commission to look at.

POPULATION and WATER SUPPLY of SUB-DISTRICTS, also DEATHS from CHOLERA, in each of the Three Weeks ending 28th July 1866.

Water Company furnishing chief Supply.	Registrars' Sub-district.	Population, 1861.	Deaths from Cholera in the week ending Saturday, July 14 1866.	July 21 1866.	July 28 1866.

NOTE.—The letters placed against the names of the sub-districts denote public institutions situated therein, namely,

W—Workhouse;
H—Hospital;
L—Lunatic asylum;
w—a workhouse not belonging to the district in which it is situated.

The following are Outlying Workhouses:

St. Geo. Hanover Sq. Workh. is in Chelsea North-west sub-dist., 2: 2.
The Strand " " Tottenham-court sub-district, 9: 2.
West London " " Islington East., 10: 2.
East London " " Hackney sub-district, 11: 4.
St. Luke, Middlesex " " Hoxton New Town sub-dist., 20: 3.
London City " " { Mile End Old Town Eastern sub-dist. 24 b: 2, and Bow sub-dist. 25: 1.
Stepney " " Bow sub-district, 25: 1.

You will see there the number of deaths in each sub-district in London of which there are 135. You will also see that the districts in the west of London, the north of London, and so on, suffered very little, whilst in every sub-district supplied by the water of this one company from the Old Ford reservoir the mortality was such as you see in the table. I went to the registrar in Bow and on requesting him to take me to some of the worst courts in the district, he said that the mortality was not confined to those courts, but that it was all over his district, that everybody more or less had diarrhœa, and that in every part of the district there were deaths from cholera. That is one of the characteristics of the epidemic when cholera poison is distributed not by contact but through the water.

2867. As far as you are able to judge, the spread of this epidemic was co-extensive with the supply of this particular water?—It was. But I should mention that the description of the supply of the East London Company is not accurate in one or two points which I will briefly explain. It was written on the evening immediately after this visit, from the best information that we possessed at the time, but of course we knew nothing of what the supply of the East London Company was, except from such publications as we had at our disposal. The statement which was made on the Wednesday attracted the attention of the Queen, of the Lord Mayor of London, and a great number of scientific and benevolent people. The Bishop of London among others, organized a system of relief, and at the same time we set to work and the Registrar-General requested Dr. Frankland to go down and determine exactly the state of the water of the East London Company; Mr. Greaves the engineer of the company came up to the office and complained that this description in the weekly report contained a misstatement as to the supply of water. I immediately showed him the source of our information, and said that if there was anything erroneous we should be very glad to put it right, that we did not at all wish to say anything disparaging of the company. He thereupon said he would write a letter, but instead of writing to the Registrar-General he wrote to the "Times," and in that letter he said that the East London Company had never for some years supplied any but filtered water from their covered reservoir. Mr. Greaves has since admitted that they did supply, as you will see, water occasionally from those open reservoirs of from seven to nine acres which are very near the covered reservoir, and that when they were in certain straits just before the cholera epidemic broke out they did get their water from those open reservoirs.

2868. Do you remember the condition of the several districts in 1849 with regard to cholera?—Yes.

2869. Do you remember what was called the cholera map, the black map, on which the places most afflicted with cholera were marked black?—Yes, we made that map.

2870. And that the cholera was most rife in those districts on the southern side of the river which were called the tide-locked districts, where the sewage arrangements were imperfect, and were the sewage was pounded back and the basements of the houses became saturated with sewage matter?—Yes, it was certainly most fatal in those districts.

2871. Since that the main drainage has been carried out in those districts and the recent epedemic did not visit it with anything like severity as compared with the years 1849 and 1854?—No; that is a remarkable and as we considered a decisive proof of the influence of the water, and it was referred to by us frequently in the weekly returns. The two companies which Mr. Simon has just mentioned, the Lambeth and the Southwark Companies, formerly supplied the south of London with water taken from Battersea and from Hungerford Bridge. In 1849 the whole of the districts of South London suffered to an enormous extent, and nearly equally in the districts supplied by the two companies. In 1849, in the cholera report, I called particular attention to the bad state of the water.

2872. Apart from the water question, was not the condition of the district at that time, from the want of drainage, most of which was under tidal influence and the basements of the houses being constantly kept saturated with filthy matter, a very exciting cause to generate and keep alive the cholera in those districts?—Yes; all the impurities that were thrown into the district were kept there and were not carried away.

2873. Apart from that district which was so heavily afflicted in the east of London, do you attribute the general freedom from cholera of the other parts of the metropolis to the drainage works as well as to the improved water supply?—Yes, drainage is an essential part of any sanitary system.

2874. Are you aware that the district which you have described in the east is just that part of the district where the main drainage is not complete?—Part of it is, not the whole of it.

2875. I mean that there is no outlet until the sewer along the Thames embankment is completed?—Part of it is so.

2876. (*Sir B. Phillips.*) Am I to understand you to say that in those districts where the cholera prevailed very largely the principal cause was the impure water?—I conceive that the cause of cholera existed here, and that the elements of disease from cholera patients were distributed all round London. Cases occurred in every part of London, but in the other districts the mortality was inconsiderable. For instance, in all the districts supplied by the Grand Junction, the West Middlesex, and the Chelsea Water Companies, the mortality was about 3 in 10,000, in those supplied by the Southwark and Lambeth Companies which were formerly so heavily visited, it was about 6 in 10,000, and in those supplied by the New River Company about 8 in 10,000, but in those supplied by the East London Company from the Old Ford reservoirs it was 79 in 10,000. I do not ascribe the whole of that mortality to the water, but I ascribe a large portion of it to the circumstance that the impurity causing cholera was distributed through the water of that company.

2877. Will you be good enough to tell us what you consider those other circumstances to be?—The density of the population also had an influence. We found that where people were packed very closely together they suffered more than where they were distributed more widely over the ground. We have found also that the condition as determined by the annual value of the houses that the people lived in, their poverty had a considerable influence, but not so striking as I should have imagined it would have had. We found also that the elevation of the ground in which the people were living had a very marked influence. In the first report I showed that the mortality on the low banks of the Thames both on the south and on the north side, was from 100 to 150 per 10,000, but as you ascended on successive terraces the mortality was reduced, and at the higher points it came down to 8, so that the elevation of the soil had a considerable influence. That I have been led to suppose since had a good deal of influence upon the purity of the water also. The East London water, for instance, is much worse in the system of pipes in the lower districts than it is in the higher districts. That I have shown in one of the tables which I have put in. Then in 1849, 1854, and 1866, if you take the water of the same company from the same reservoir you will find that the mortality of the people supplied by that water is greater in the low districts than in the high.

2878. (*Col. Harness.*) Where the two sources are equally good?—Yes. I have a tube containing about a hundredth part of cholera matter, which looks like a milky sort of substance; and I should mention that that tube shows the matter in suspension; it is almost clear at the top and it gets a little thicker and assumes a pearly opalescent appearance as

Dr. W. Farr.
May 1867.

you descend. I think that anything like impurity of that sort in suspension in water exists in greater quantities in the lower pipes than it does in the higher pipes.

2879. (*Sir B. Phillips.*) Did it not occur to you that owing to the destitute circumstances of those poor people, and their emaciated condition from want of animal food, many of them also being addicted to gin drinking, when they were attacked by any character of disease they had no strength to resist it?—That was a great cause of the severe mortality.

2880. Do not you think that that had a very material influence upon the mortality, irrespective of the water?—Yes, irrespective of the water it had a very considerable influence, but the same elements existed in contiguous districts supplied with other water without causing this enormous mortality, and it is the enormous mortality which we are endeavouring to account for.

2881. (*Mr. Harrison.*) Was it not the case in particular districts in the visitations of 1849 and 1854 that houses adjoining each other were supplied by two different companies, and did you not find throughout the whole of that district, house by house, that the mortality in the houses supplied by the one company was infinitely greater than where they were supplied by the other company?—Yes, certainly. I should say that the Southwark and Vauxhall Companies were in competition on the south side of the river, and that they often supplied the same street, where the condition of the people was precisely the same in the houses supplied by the two companies. There was so little difference that the people themselves sometimes did not know by what company they were supplied. The Lambeth Company, as you are aware, up to 1852 took its water from the river here, near Hungerford Bridge, I suppose the impurest part of the river probably. In 1849 I recollect going up to Brixton and other places, where there had been two or three deaths in a house. A merchant of London and his wife both died, and when I went to the house I saw the daughter, and on inquiring into some circumstances connected with the case, she brought me some of the water in a tumbler, and it had quite a milky appearance. It had come from the reservoir up at Brixton, and probably contained cholera matter. It contained matter out of the river, at any rate, and we found that the case in a great number of those houses at Brixton which were supplied by the Lambeth Company. After this, as their water was the worst, they were the first to move in the matter, and they went to Parliament and got power in 1852 to go up the river above Teddington. When the epidemic came in 1854 we found that it would be an excellent opportunity for determining the effects of the water, as the two companies supplied the same district, and the houses were nearly of the same class. Dr. Snow, who had started this theory of the distribution of cholera through water came to us, and we gave him every facility for making inquiries, and he went over the houses in the streets supplied by the two companies, and I will just state the result. In 1854 the Southwark Company continued to get its water from Battersea, close to one of the sewers, but the Lambeth Company had gone up to Teddington, beyond the range of the London sewage. In 1849 Bermondsey was supplied by the Southwark Company, and the deaths from cholera were 734, and in the 14 weeks ending the 14th October 1854 they were 829; the number of deaths was greater in 1854 than it had been in 1849. In Lambeth it was found that being supplied by the two companies, and only partly by the Lambeth Company, the deaths in 1849 were 1618, and in 1854 only 904. Then I state in my letter to the Registrar General on the cholera epidemic of 1853–54. "Dr. Snow, who has devoted "much time to the investigation, having procured "from this office the addresses of the persons who died "of cholera in Kennington, and some other sub-"districts, states, as the result of an inquiry from "house to house, where the pipes of the Lambeth "Water Company are intimately mixed with those "of the Southwark Company, that in the seven "weeks ending August 26th, of 600 deaths from "cholera, 475 have happened in houses supplied "by the Southwark Company, 89 in houses sup-"plied by the Lambeth Company, 13 in houses "supplied by pumps, wells, and springs; 8 in "houses which derived their water directly from the "Thames and from ditches. The registrars on the "south side of London were instructed to inquire in all "cases of death by cholera" and into the water supply. In many cases they could not get the information, as the people did not know which company supplied the water, but this was the general result. I should state that the Lambeth Company supplied 26,000 houses, and the Southwark Company 40,000 houses. The deaths from cholera during six weeks in the houses supplied by the Southwark Company were 2,284 in 40,000 houses, while 294 deaths occurred in the houses supplied by the Lambeth Company out of 26,000 houses. The proportions are these, to every 1,000 houses supplied by the Southwark Company there were 57 deaths from cholera, and to every 1,000 houses supplied by the Lambeth Company 11 deaths. We afterwards got a return from the companies of the houses they supplied, and we ascertained the number of deaths in those houses from our books, and the general result was summed up in this way, that in the houses supplied by the Lambeth Company the deaths were 12 per 1,000 in 1848–9, and in 1853–4 only 4 per 1,000. In the case of the houses supplied by the Southwark Company the number of deaths per 1,000 was 12 in 1848–9, and 13 in 1853–4, so that the Lambeth Company had fallen from 12 to 4 while the Southwark Company had got worse. That seemed a decisive and conclusive experiment, showing the influence of the supply of water in a cholera epidemic. It was that which enabled us so decisively to say that the East London districts which were affected in the same way precisely as those in South London had been, must have been affected through the distribution of the poison by the water. We went on with the inquiry week after week, getting all the information on the subject we possibly could, and the conclusion to which we had been lead at the first was fully confirmed. I should say that the very week after Mr Greaves, who grew fully alive to the importance of the subject, came up, the cholera epidemic in the east of London began rapidly to decline whilst it remained stationary in the rest of London. The conclusion we came to was, that the Company had resorted to those open reservoirs which contained dirty water, and distributed it for a certain time more or less in a certain number of days, but then they took such precautions as led gradually to the purification of the water, and the water in the end became as good as that of the other companies, and the mortality declined.

2882. (*Sir. B. Phillips.*) Do they get their water from the same source still?—Yes; the water, until it comes down to the Old Ford reservoir, as far as we could see and learn from its effects upon the population, was as good as that of any other company, but when I went down there the river Lea was full of the sewage of West Ham, which had been poured into that river, and it was going up and down within a very short distance of the reservoirs of the East London Company; the banks were gravel and loose, and of course the impure water from the Lee got into the open reservoirs, and as Captain Tyler has since discovered, got into the covered reservoir.

2883. (*Sir J. Thwaites.*) Has your attention been directed at all to the question of hard or soft water, and their effect upon the human system?—I have often thought it most important to endeavour to determine the effect of hard and soft water on health, but at present I am not satisfied that we are able to state the precise effect of hard and soft water on health. I heard a gentleman here mention that stone had been said to be prevalent in chalk countries, and I know that a paper was written on the subject, and published in the transactions of the Royal Society,

showing that there were more stone cases and cases of lithotomy in Norfolk than in some other counties: but there was no registration of the cause of death at that time; the means of registration were very imperfect, so that I do not feel that we are at present able to say what is the precise effect which lime and other substances of that sort have upon health. I think the subject ought to be investigated.

2884. Do you think there really are more cases of stone in Norfolk than in other counties?—I am not satisfied that the fact is established.

2885. (*Mr. Harrison.*) Your view is generally that those waters in which human excreta enter to any extent are dangerous?—Decidedly.

2886. Do you think that the filtration through earth from applying the sewage to the land as manure would take away all the dangerous effect, or would you consider that after being filtered through the land there would still be a dangerous tendency in the water?—I should not think the danger considerable if it passed through a certain thickness of earth. I should not conceive that the danger would be very great, or indeed any such as need deter us from using the water, but if manure is put on the land it would be washed down in certain cases into the rivers.

2887. That would depend would it not upon the nature of the soil?—Yes.

2888. But with regard to a chalk soil you would have no fear whatever?—Certainly not.

2889. On a clay soil you might find a great deal of the sewage brought off in cases of flood?—Yes.

2890. (*Sir B. Phillips.*) Do you think that if this London water could be free from all its impurities it is a good quality water for consumption?—I confess that when I see that this Loch Katrine only contains in 100,000 grains three grains of impurities of any kind, and that it contains no trace whatever of sewage or anything like sewage, I should have greater confidence in water brought in that way from the hills than I should in water taken from the river; at the same time I am not prepared to say that the water from the river, with great precautions as to letting sewage into it, might not be made a very decent sort of water.

2891. (*Sir J. Thwaites.*) Is your confidence in the hilly districts as a gathering ground, or is it in the condition of the water?—The water would be purer there.

2892. My question had reference to the gathering ground being freer from any vegetable decomposition?—In Scotland and Wales, and other places in the mountainous districts where the rain is perpetually coming down in torrents the water is pure, and it evidently, I should think, is in the best possible state for the supply of our wants, both for drinking purposes and for domestic purposes of every kind.

2893. And it must of necessity be purer than any water from the Thames basin, having regard to the state of cultivation in that area?—Necessarily so; I think more danger lurks in the Thames water. I will just mention the difficulty in keeping out impurities by referring to a little stream which I know, the Ravensbourne: the water of the Kent Company is now the worst water according to Dr. Frankland, but I believe they say that they do not use the Ravensbourne, and if they do they take great precautions in filtering it. But up to the very heads of the streams the people are putting their closets or drains and pouring them into those small streams, and it is almost impossible to prevent them. There is a stream at Bromley, for instance, which I noticed the other day, and there is a watercloset over it in a small cottage where I believe there were several deaths from cholera in 1849: it is almost impossible to prevent the pollution of the heads of such rivers. It will be an immense advantage, no doubt, if those measures are carried out for which an Act has been obtained, so far as keeping out the great town sewers from the Thames is concerned. The evils we suffer from are felt on the Seine. I believe that our water is much purer than the Paris water; there is no doubt about that.

2894. (*Mr. Prestwich.*) You mean the water that they were using in Paris, not the water that they are now using?—The last outbreak of cholera was caused by impure water and they still get water from the Seine.

2895. Are you not aware that they have now made an aqueduct to bring water from the chalk districts?—Yes, a certain portion of it, but it is not so much as one would be led to suppose from the way in which they speak of it. You will see by the report that the larger proportion is taken from the Seine and the Canal de l'Ourq. A gentleman who has written a very good book on the subject has shown that in proportion as the Seine gets low in water the sewage discharged remaining the same, the water of course became impure, and just at the time of the maximum impurity of the Seine water, that explosion of cholera which we remember, took place in Paris.

2896. (*Mr. Harrison.*) Taking the case of Glasgow, the death-rate by this return which you have put in is 31 per 1,000?—Yes.

2897. And the next to that is Newcastle-upon-Tyne, 28 per 1,000?—Yes.

2898. Taking it that both those towns are supplied by a constant service, and that in the case of Glasgow the water is the purest of any supplied in the kingdom, is it not obvious that water forms only one of the elements in the sanitary state of a town?—It is quite clear that it is so, and that is why I say that an investigation is necessary, and I think that you have the means of almost determining the effect of comparatively pure water. I have here a return for 52 weeks of the year 1866, of the mortality in Glasgow and now in London, by which it will be seen that the mortality in Glasgow is 30 on the average, and it was high before they got this water from Loch Katrine, and the mortality in London was 26.

2899. (*Sir J. Thwaites.*) There you have the contrast still greater, as they have a purer water in Glasgow than we have?—Yes.

2900. (*Col. Harness.*) Have you made a comparison of Glasgow before and after the introduction of the Loch Katrine water?—No. This subject of the influence of pure water and of soft and hard water requires investigation, and the Commission has the means of carrying out that investigation.

2901. You stated that there are some data to begin with, have you classified them?—No, not so as to satisfy my own mind. In the case of Glasgow you would think that all the people of Glasgow got this water—soft water—but I believe they do not.

2902. (*Mr. Harrison.*) Now they do, do they not?—Yes, in taps at the bottom of the houses, and so on, but it is not distributed over the houses, so as to have the same effect as it has in other districts.

2903. (*Sir J. Thwaites.*) They have merely standcocks in courts?—Yes, and it is necessary to go into all those details before you can say whether the town is thoroughly supplied with pure water, or not; it is brought there, but whether it is distributed so as to produce all its beneficial effect is another question.

2904. (*Col. Harness.*) But Glasgow receives no other water, does it?—No other water is now used on the north side of the Clyde. On the south side, Dr. Gairdner informs me that "Gobals gravitation water" is still in use.

2905. (*Mr. Harrison*). They have the largest supply of water per head, have they not, of any in the kingdom, amounting almost to 50 gallons per diem?—Yes. Dr. Gairdner, the health officer of Glasgow, I should think would be prepared to tell this Commission what has been done in supplying every house in Glasgow with water, and also to trace its effect; and, in Manchester, you would also have an opportunity of showing the effect of pure water without a proper system of sewage. As Sir John Thwaites very properly noticed it is necessary that the two should be combined in order to get the maximum effect.

2906. (*Sir J. Thwaites.*) In Glasgow the condition of the river, and the great want of drainage in the town had to be taken into account, and that might

have aggravated the epidemic?—Yes, and no doubt the crowding of the population must have had another bad effect.

2907. (*Mr. Harrison.*) And possibly the whiskey being cheap had a bad effect in many cases?—No doubt that had its effect, but I constantly see those partial efforts of reforms: even in the metropolis where we have such a capital system of sewage to a certain extent, the full advantage of that, as we have often noticed, is not felt because those sewers are not in communication with every house, as they ought to be.

2908. (*Sir J. Thwaites.*) That is becoming very rapidly accomplished, is it not?—Yes. I think of investigating the matter scientifically in order to see what the effect of the system of sewage is, for instance, when it is properly carried out to every house so as to produce its maximum effect. And also with regard to the water supply, if you carry your pure water to every house, and let people have an adequate supply of it you ought to experience its full effect; but you will never experience its full effect till you join with it a system of sewage such as you have in the south of London. And you have got an enormous difference which I should like to mention where you have the two combined, that is to say, the drainage and the water supply. I will read this extract from the Registrar-General's weekly table for December 8th, 1866, at the end of the epidemic: "A "most gratifying and conclusive proof of the good "effects of improved water supply is afforded by the "experience of the South London districts which "were undrained, and were supplied with the foul "sewage water of the Thames by the Southwark "and Lambeth Companies in 1849." There you had the maximum of evil—you had bad water and no drains. Then the mortality by cholera in 10,000 inhabitants was 120. I believe that the drainage of South London was not carried out in 1854. There were great improvements in the local drainage, but not in the outfall. Then the mortality when the purer water was supplied by the Lambeth Company fell from 120 in 1849 to 87 in 1854, and in 1866 it was reduced to 8 in 10,000. From cholera and diarrhœa the deaths out of the same numbers living in that district, with the maximum effect of bad water and imperfect drainage, were 142, in the intermediate period 104, and in the last period 15. As the water improved and the drainage the deaths declined to this marvellous extent. Similar if less striking evidence of the effects of pure and impure waters is supplied by the experience of the other London companies.

2909. (*Col. Harness.*) Did you receive the same detailed information of the deaths and the cause of death from Glasgow that you did in London?—The Registrar-General of Scotland does now.

2910. Did he before the Loch Katrine water was introduced?—He did not; but they had a local system of returns—a very valuable one, indeed—one of the first in the kingdom; and they had the means of comparing the rate of mortality.

2911. They had the means of comparing what the state of disease was, all other things being the same?—Yes.

2912. (*Sir J. Thwaites.*) Have you not that return in your office?—No. The Registrar-General for England only receives the returns for England.

2913. The Scotch returns are published, are they not?—Yes.

2914. You have a printed copy of them, have you not, at the office?—Not for the exact municipal boundary of Glasgow.

2915. Could you put it in your evidence, so as to give what Colonel Harness suggests, namely, the contrast between the mortality in Glasgow prior to the supply of the Loch Katrine water and since?—If you will allow me I will write to the Health Office at Glasgow, Dr. Gairdner, or the Commission might write, and ask him to send the information up to you; I will do all I can to supply the information that the Commission desires.

2916. (*Mr. Prestwich.*) Could you not furnish the Commission with returns from towns which have been supplied with soft water within a late period, such as Manchester and Newcastle, showing the same comparison?—We could supply the information as to diseases and mortality.

2917. (*Sir J. Thwaites.*) Take Hull for example, could you give us the result there?—At Hull the result is very decisive, we have had no cholera at all of any account in the recent epidemic of last year. The deaths from cholera in the districts of Hull and Sculcoates in the three epidemic years 1849, 1854, and 1866, were 1,834, 27, 21.

2918. (*Mr. Harrison.*) Ought not such a return to contain the quantity consumed per head before and after the change in the supply?—Yes, and the distribution; I think you ought to get that from the towns to make it of any use.

2919. (*Sir J. Thwaites.*) However, you can give the Commission the fact that in the year 1854 the mortality in certain towns was so many in each 1,000 of the inhabitants, and that since the supply of water of certain quality the mortality has increased or decreased?—Yes.

2920. And also its influence on the several diseases?—Yes, as far as I can find it out. It is necessary that I should know in what years the supply was changed.

2921. Will you take a reasonable number of years before the supply was changed and after so as to give the result of a fair average?—Yes.

2922. (*Mr. Prestwich.*) How far back do your returns go?—To the year 1837.

2923. (*Mr. Harrison.*) Such an investigation as you suggest of the whole question is necessarily one of a scientific character of the utmost nicety?—Yes.

2924. And also one that would require considerable time?—Yes.

2925. Do you think it possible that this Commission could make that inquiry sufficiently satisfactory, or are they a sufficiently scientific body to make it. Is not that more an investigation for a commission of medical men?—I think not for medical men only. The course which we have pursued generally on commissions with which I have been connected has been to appoint some one to conduct special inquiries for us. In the commission on the sanitary condition of the Indian army we employed people to conduct those inquiries and to devote their time to them. The Commissioners of course could not devote the whole of their time to them.

2926. The view which you present in your letter to the Commission is that some of the effects of water are immediate and easily perceptible; others are slow and are some time before they take effect; and finally, others are only felt as they operate on the young and on successive generations?—Yes.

2927. That is an extent of inquiry which it is quite obvious that this Commission could not arrive at any satisfactory conclusion upon?—They would employ proper persons to do it for them. The effect of bad water on children of different ages is very different. I believe that the worms which afflict children in certain towns enter them through the impure water.

2928. A change of water, as is well known, has an effect upon people. For instance, on changing from a soft water to a hard water, going into a limestone district where the water comes from the magnesium limestone, many people are made ill for a time?—Yes, and that has an effect on animals also no doubt. I remember going over John Day's training establishment at a time when he had some hundred horses training. His establishment was situated on the chalk where the water was hard, and when I asked him about the water that the horses drink he said that he gave them nothing but rain water, that they would not drink the hard water, and he found that a perfectly pure water suited the horses best. I do not know what other trainers do. The character of the water no doubt has a great influence on the strength and health and vigour of man, and I do not think that

we have yet determined the precise effect of hard water on the human constitution.

2929. (*Mr. Harrison.*) As far as your experience goes, are we to take it that this view which is conveyed in the report of Dr. Frankland is one that you concur in, namely, that at the present moment taking his analysis there is nothing that is really bad in the water supplied to London?—Not on that particular day. I should qualify it myself always in that way. I can conceive that the character of the water varies from day to day; it varies with the temperature and with the rainfall, and with a variety of circumstances. All we know is that from the analysis which Dr. Frankland has hitherto made he has come to the conclusion that the water supplied to London has contained something very noxious, but that it did not contain anything noxious at the time that he took it at the mains. Professor Abel at Woolwich tells me that he finds an essential difference in the chemical character of the water pumped from the chalk at different states of the tide in the Thames, showing that there is a communication in some way or other through the chalk into the wells which are in proximity to the Thames.

Dr. W. Farr.
8 May 1867.

2930. (*Col. Harness.*) So that water affected by the Thames as it passes through that country may be affecting the water drawn from the chalk wells?—It might do so.

The witness withdrew.

Adjourned to to-morrow at 11 o'clock.

Thursday, 9th May 1867.

PRESENT:

SIR JOHN THWAITES IN THE CHAIR.

Colonel HARNESS.	THOMAS ELLIOT HARRISON, Esq.
Alderman Sir BENJAMIN PHILLIPS.	JOSEPH PRESTWICH, Esq.

JOHN THORNHILL HARRISON, Esq., examined.

J. T. Harrison, Esq.
9 May 1867.

2931. (*Chairman.*) You are a civil engineer, are you not?—I am.

2932. And you are one of Her Majesty's Commissioners on the pollution of rivers?—I am.

2933. You have made your report have you not?—We have made reports upon the Thames and of the Lea.

2934. Have those reports been published?—They are both published. The report upon the Lea has been presented to Parliament, and I suppose will soon be distributed; I can lay a proof copy of that report before the Commission (*handing in the same*).

2935. You have had your attention directed, have you not, to the water supply of the metropolis, especially from the Thames basin?—We have. That subject was referred to our Commission in part in consequence of a letter written by Mr. Neate, the member for Oxford, which you will see at the commencement of our reports.

2936. Your attention then was directed to the necessity for purifying the river and intercepting all the sewage and other polluting matter which finds its way at present into the river, and you have reported as to the means of interception?—Yes, we have done so; that is the primary object of our Commission; the water supply is a secondary object to be carried out so as not to interfere with the first object, namely, that of remedying the pollution.

2937. Then the water supply was a secondary object with your Commission?—Yes.

2938. But you did, I suppose, examine that question in connexion with the purification of rivers?—Yes, and in consequence of instructions from Sir George Grey, whenever we had an opportunity of gaining information during our inquiry we took the evidence that was tendered to us.

2939. You have done so agreeably to the letter dated Whitehall, July 7th, 1865, signed H. Waddington, giving your Commission additional instructions with reference to that subject?—Exactly so.

2940. In connexion with the water supply, has your attention been directed to the capacity of the Thames basin to yield a sufficient supply of water for the metropolis?—Yes, during our inquiry we received a considerable amount of information upon the subject, this I have endeavoured to put together, so that we (the Rivers Pollution Commissioners) might draw conclusions for our future report upon the subject of water supply.

2941. Have you tabulated the information which you obtained for the purposes of your Commission?—Yes.

2942. And I suppose you are prepared to hand in a copy of those tables for the use of this Commission?—Yes.

2943. Your attention was necessarily directed to the rainfall in the district?—It was so.

2944. Can you state to this Commission what steps were taken by you or the data upon which your calculations were made with respect to the rainfall in the area of the Thames?—Mr. James Simpson, who is Engineer of the Chelsea and Lambeth Waterworks Companies, offered during the inquiry, and subsequently sent in a return of the daily rainfall at Kingston-upon-Thames for 11 years, from 1855 to 1866.

2945. That was taken, I presume, at the waterworks?—Yes, near the waterworks, and I subsequently, (not during our inquiry,) in conversation with Mr. Brown, of Cirencester, found that he (Mr. Brown) had, during the same period, kept an accurate daily record of rainfall at Cirencester throughout the same 11 years, and he very kindly sent me these observations for the use of the Rivers Commission.

2946. That would refer, would it not, to the upper part of the Thames?—Yes.

2947. Have you had any information as to the other parts of the basin?—We obtained information from other parts, but from no source giving the daily rainfall as obtained in those two instances.

2948. Not with anything like regularity?—No.

2949. You had not reliable data?—I have not.

2950. Then the two gauges which you refer to would appear to represent the two extremes of the valley, that is to say, the lowest point and probably highest?—Not quite the highest, but it would be a fair average of the upper part of the basin. I thought that the two records would represent fairly an average rainfall of the whole Thames basin.

2951. Can you give us the result of those two gaugings?—I will lay before the Commission Table No. 1.

The witness delivered in the following table:

W. T. Harrison, Esq.

9 May 1867.

No. 1.—Table showing approximately the Monthly Average Rainfall, in Inches, on the Thames Basin in each Month, from April 1855 to April 1866.

Year.	April.	May.	June.	July.	August.	September.	Totals.
	Inches.	Inches.	Inches.	Inches.	Inches.	Inches.	Inches.

Average	3·260	2·110	1·850	2·410	1·660	1·960	13·24

Total rainfall in 11 years was 304·18, averaging 27·65 inches per annum.
February, on the average, is the driest month; October decidedly the wettest; the order being February, April, December, March, November, July, January, May, September, August, June, and October.

Note.—This rainfall is calculated from an average of the records kept by James Simpson, Esq., C.E., at Kingston-on-Thames, and by Thomas Brown, Esq., at Cirencester.

2952. (*Mr. Harrison.*) Will you explain the nature of this table?—This table (No. 1.) gives approximately the average rainfall of each month during 11 years upon the Thames basin.

2953. That is embodied, is it not, in two periods of the year?—Yes, one period, the summer months from April to September inclusive, and the other from October to March, inclusive. The result of the addition of those, and averaging them over the 11 years, shows that the month of October is decidedly the wettest month of the year, the rainfall being considerably higher than in any of the other months. It shows also that February is the driest month.

2954. And the average rainfall of these years is what?—27·65 inches per annum. The rainfall at Cirencester is about four inches more than the average at Kingston, but there were one-half more days upon which rain was recorded at Kingston than there were at Cirencester. This is easily accounted for, as the heaviest rain comes from the west, and Cirencester being about 360 feet above Ordnance datum and much to the westward of Kingston, receives the larger rainfall, but Kingston, from its position, receives showers both from the east and west.

2955. (*Chairman.*) Is there anything at the point where the upper gauge is fixed to deprive it of the advantage of those eastern showers?—I take it that the eastern showers do not reach so far; the western rainfall is much heavier.

2956. Then it becomes exhausted before it arrives at Kingston?—Partly so.

2957. (*Mr. Harrison.*) The general result of this table is to show that in the months from April to September the average rainfall is 14·40 inches, and from October to March 13·24?—Yes.

2958. The two together making 27·65 as the average rainfall over the whole of the 11 years?—Yes; I think before going to Table No. 2, it would be well if I were to put in another, which I will call No. 1A.

The witness delivered in the following table:

No. 1A.

Table showing the Rainfall, Percolation, and Evaporation, in Inches, during the Years 1861 to 1865, inclusive, at King's Langley, as recorded by John Evans, Esq., and at Lea Bridge, as recorded by Charles Greaves, Esq., C.E.

Average percolation at King's Langley, 29 per cent.; average evaporation 71 per cent.
„ „ Lea Bridge 28·8 „ „ „ 71·2 „

Note.—According to Mr. Beardmore's observations the proportion of the rainfall which actually flowed into the river from the Lea Basin in the years 1851, 1852, 1856, and 1858 was on an average only 18·5 per cent.

2959. (*Chairman.*) Will you be good enough to describe that Table No. 1A?—In addition to the daily record of rainfall at Kingston and Cirencester from Mr. Simpson and Mr. Brown, Mr. Evans kindly gave me the monthly record of percolation at King's Langley, which I have made use of in the subsequent tables; but during our inquiry on the Lea, Mr. Greaves, who is the Engineer of the East London Waterworks, gave us his observations on percolation for several years. This table (No. 1A.) has side by side the observations of Mr. Greaves and of Mr. Evans, and you will observe that the results strikingly accord. The average rainfall at King's Langley during five years was 23·72 inches, and the average rainfall at Lea Bridge 23·15 inches. That was for the five years from 1861 to 1865 inclusive. The percolation observed by Mr. Evans at King's Langley was 6·88 inches, and the percolation at Lea Bridge as reported by Mr. Greaves was 6·66 inches,—the difference between the rainfall and percolation they give as evaporation—that at King's Langley being 16·84 inches, and that at Lea Bridge 16·49 inches.

2960. How do they arrive at the absorption or percolation as you call it?—The Dalton gauge used by Mr. John Evans is a cylinder 18 inches in diameter, turned to a knife edge at the top and sunk to a depth of three feet below the level of the ground, filled with fragmentary chalk and covered with grass similar to the surrounding ground. The rain which passes through is collected in a gauge and measured from time to time, the rainfall on the surface at the same time being recorded.

2961. I presume they take the quantity measured at the bottom of the trench as that which is absorbed and all plus that they give as evaporated?—Yes evaporated or taken up by vegetation. The average percolation at King's Langley for the five years is 29 per cent. and the evaporation 71 per cent. The average percolation at Lea Bridge is 28·8 per cent. and the evaporation 71·2 per cent.

2962. If I rightly understand the object of this test, it is to ascertain the absorbing power of the land in that area and the amount of evaporation, in order to ascertain what would really be available as a water supply?—Quite so.

2963. Can you give us, in figures, the net result that would be available for a water supply, or that finds its way into the rivers?—Yes, that will come in subsequently. I may mention here that the object of Mr. Evans and his predecessor Mr. Dickenson was to ascertain what quantity of water they could rely upon during summer seasons for working their water-wheels, they being large paper manufacturers at King's Langley, and those observations were made with that object. The greater number of the observations I have used are reported in the transactions of the Institution of Civil Engineers; the additional observations complete the table up to April 1866.

2964. You have no doubt, have you, that those investigations have been conducted with intelligence and fair accuracy?—I believe so, the object of the parties conducting them being to arrive at the truth.

2965. As far as you are able to judge from the returns made, those gentlemen appear to understand the subject?—Yes, the subject has been frequently discussed at the Institution of Civil Engineers, and I believe the records are reliable.

2966. (*Mr. Harrison.*) I see a note appended to this table (No. 1A) which is to this effect: "According "to Mr. Beardmore's observations, the proportion of "the rainfall which actually flowed into the river "from the Lea basin in the years 1851 and 1852, "1856 and 1858, was, on an average, only 18·5 per "cent." ?—Yes. You will observe that those are special years, they do not refer to the years mentioned here, and therefore I put that down as a note. Mr. Beardmore gave it in evidence before the Rivers Commission on the Lea inquiry. I will now hand in Table No. 2.

The witness delivered in the following table:—

No. 2.

TABLE showing approximately the RAINFALL on the THAMES BASIN, the DISCHARGE by the THAMES at KINGSTON, the EVAPORATION and the ADDITION to or SUBTRACTION from the SUBTERRANEAN RESERVOIRS in Inches over the entire Surface, half-yearly and yearly, from April 1855 to April 1866.

One inch of rain over the Thames Basin (area 102,480,000,000 square feet) gives 53,375,000,000 gallons of water.

NOTE.—The rainfall is calculated from the average of the records kept by James Simpson, Esq., C.E., at Kingston, and Thomas Brown, Esq., at Cirencester.

The discharge is calculated from data supplied to the Rivers Commission by James Simpson, Esq., C.E.

The evaporation is calculated from observations on percolation by John Evans, Esq., of King's Langley, with an addition for extra evaporation from the clay in winter.

J. T. Harrison, Esq.

9 May 1867.

2967. (*Chairman.*) Will you explain Table No. 2?—In Table No. 2 the rainfall in inches is given half-yearly, and also yearly in the first two columns. In the third and fourth columns is given the discharge at Kingston. I should explain to the Commission that, during our inquiry on the Thames, Mr. Simpson stated to us that he had made observations daily at 9 o'clock in the morning since 1855 as to the height of the water in the Thames above the point where the Metropolitan water companies take their supply near Kingston.

2968. Had he a careful section of the river at that point?—Yes, and with the permission of the Commission I will put it in (*handing in the same. See Appendices A, B, 1 and 2*). He gave to us this longitudinal section of the Thames, and these cross sections at the point where the observations were made.

2969. Near to their works, I presume?—Yes, above their works; some miles above Teddington Lock.

2970. There would be no difficulty in calculating the exact quantity that passed that point marked, having a careful section of the river?—I would not say that it was exact, but I am sure that the result is approximately true. His observations are exact for every day during the 11 years from 1855 to 1866.

2971. Can you give us the result of those observations?—Mr. Simpson gave us some observations as to the velocity of the water when the river was at certain heights. From Mr. Beardmore's tables I calculated what the volume of water passing daily would be when the river was at different heights, and from the volume so calculated I have made this diagram No. 1 which shows the daily flow of water past Kingston during those 11 years (*describing the diagram to the Commission*).

2972. (*Mr. Harrison.*) Would the red line divided into days give the actual flow in gallons at that point for every day for the 11 years?—Yes, if you draw a perpendicular line at any date from this base, the height from the base line to the point where the perpendicular line cuts the section, shows the volume of water passing down the river Thames that day. The blue is the average daily rainfall during each month.

2973. What does the blue represent?—The blue represents the actual volume of water that fell upon the whole of the Thames basin during each month.

2974. (*Col. Harness.*) Therefore it was a flood at that point?—It might or might not be a flood the whole way up.

2975. How do you explain it, that here we have got a flow greater than the rainfall?—I think I can explain it to you.

2976. (*Chairman.*) This diagram represents the flow in all cases at Kingston?—Yes, every day.

2977. (*Col. Harness.*) But this (*pointing to the diagram*) is taken, is it not, from the whole basin above Kingston?—The date of that flow is about the middle of February 1856. Those little marks at the bottom of the diagram represent in parts of an inch the daily rainfall. The brown at Cirencester, and the red at Kingston. They show that the flood was chiefly from Cirencester, as there was comparatively little rain at Kingston, but heavy rain was falling in the middle of February, when the ground was saturated, and probably the greater part of the water that fell on the surface flowed off.

2978. (*Mr. Harrison.*) In order to arrive at that you must go back, must you not, even for weeks before?—Yes.

2979. (*Col. Harness.*) Is not this owing to the arrangement of the two scales, the two scales do not show the relative proportion?—They do not show the relative proportion of the rainfall and discharge each day.

2980. If we forget the red and look at the blue we have the relative quantity of the red, and if we look at the red and forget the blue we have the relative quantity of the blue, the two will not lie one upon the other?—Quite so. But this was the only way in which I could show the average; it sometimes may happen that there is a larger discharge than the rainfall would show for the particular time. For instance, when there is a copious discharge from the springs, a comparatively small rainfall raises the river, producing almost a flood. When the springs are very low, and the ground very dry, as was the case in September 1865, there may be very heavy rainfall, showing hardly any flood, the water being evaporated or absorbed by the land.

2981. (*Chairman.*) That is dependent upon the absorbing power of the ground?—Yes.

2982. When the ground is saturated of course the quantity of rain that falls must necessarily run off?—Yes. You will observe that in September 1865 there was hardly any rainfall and the river was extremely low, and the ground was parched. There was the heaviest rainfall recorded throughout the whole 11 years in the October following, but with hardly any result in the way of increasing the volume of water flowing down the river. The land was exceptionally dry, and consequently capable of absorbing and evaporating to the uttermost.

2983. (*Mr. Harrison.*) The diagram shows that September was an exceedingly dry month. Then comes the largest rainfall in October which does not cause a flood until the land becomes saturated after two or three months?—Yes, that is quite in accordance with the evidence received from Mr. Bailey Denton, that on some clay land which he occupied he found after that dry September it required 6 inches of rainfall before the ground was so saturated that it would pass any water by the under drains at a depth of about 4 feet 6 inches below the surface.

2984. (*Col. Harness.*) Will not the returns appear in the report of the Rivers Pollution Commission?—Yes, but as this Commission have taken up the subject, I have spoken to my brother Commissioners, and they are quite willing that you should be able to make any use of the returns you wish.

2985. (*Mr. Harrison.*) Those tables were prepared for the purpose of the report?—Yes; but if we have prepared anything that will forward the object of this Commission, you are welcome to it. After the ground is thoroughly saturated by a heavy and general rainfall, and after the rain has ceased, the gradual diminution in the volume of water passing down the Thames when shown on a diagram forms very nearly a regular curve; this I have represented approximately upon diagram No. 2. (*this the witness handed in. See Appendices A, D*). Diagram No. 2 shows the volume of water passing at each successive period during 240 days which would elapse subsequent to a heavy flood before the discharge of the river would be reduced to about 350,000,000 gallons per day.

2986. (*Mr. Prestwich.*) As you have only taken the rainfall at two points, at Kingston and Cirencester, have you found any anomalies to arise in the relation between the rainfall and the delivery of the river at Kingston from excessive local rainfall on any of the tributaries, such as the Kennet, the Colne, or the Wey?—I have not been able to examine that, but there is one striking feature that diagram No. 1 brings out, which is this, that when the rainfall is chiefly at Kingston, the river rises and also falls much more rapidly, apparently from the rain falling upon London clay and passing more rapidly down to the river. Diagram No. 2 would not apply to this; it would not be found sharp enough to represent a rainfall immediately in the neighbourhood of Kingston when there was no rain at Cirencester; in such cases the flood passes off very rapidly, in fact in a few days.

2987. (*Col. Harness.*) That is applicable to the general rainfall throughout the whole district?—Yes.

2988. (*Mr. Prestwich.*) I mean rather this, that in case of an excess of local rainfall in any of the tributary valleys, such as the valley of the Wey, or the Colne, or the Kennet, have you found that to interfere with the results given on this table?—I have

no information which would enable me to make any reliable observations upon that point.

2989. (*Mr. Harrison.*) Referring to Table No. 2, you explained the columns 1 and 2 as being the result of the rainfall over the 11 years, divided in the first column into the months between April and September and as between October and March, and the second column gives the yearly rainfall in inches?—Yes.

2990. From that it would appear that in 1866 the maximum rainfall of those 11 years was 36·42 inches?—Yes.

2991. And the minimum appears to have been in 1857, when it was only 22·76?—Yes.

2992. The average being, as has been stated already, 27¾ inches?—Yes.

2993. Taking the next as the calculated discharge at Kingston, that, I presume, is taken from the information which you have already put in as obtained from Mr. Simpson's observations?—Yes, reduced to inches over the whole area of the Thames basin.

2994. Therefore, that gives the discharge in inches at Kingston as being 9·25 inches out of the 27·74 inches?—Yes.

2995. Then the remainder is 18 inches?—It is not the exact remainder. The next two columns, half-yearly and yearly, are taken chiefly from the information given by Mr. Evans. You will observe there is this note: "The evaporation is calculated "from observations on percolation by Mr. Evans of "King's Langley, with an addition for extra eva- "poration from the clay in winter." There would of course be a larger evaporation from the clay than from the chalk.

2996. (*Chairman.*) Because of its retentive power? Yes, and the water lying longer and being more exposed. Mr. Bailey Denton's observations on the discharge from free soils and from clay soils clearly prove that there would be a larger evaporation from the clay during winter. Therefore, I have added as nearly as I could calculate it (and I have done it pretty carefully) the extra evaporation from the area of the clay basin.

2997. (*Mr. Harrison.*) Then going on to the fourth which is the volume added to or drawn from subterranean reservoirs half yearly, being plus or minus, I presume that column represents this, that where it is plus it must be due to taking a large amount from the chalk chiefly to make up the difference?—Where it is plus it shows that there was an addition to the subterranean reservoirs, and where it is minus it shows that the chalk gave out more than it received.

2998. Taking the whole of those calculations together, they account for the whole of the 27¾ inches?—Yes.

2999. When there has been a wet season, a portion of it is absorbed by the chalk or the oolite, or whatever the soil may be, and again in dry seasons is discharged from them, making up this plus or minus amount?—Yes.

3000. (*Col. Harness.*) Is plus and minus applicable to the reservoir or the river?—To the subterranean reservoir.

3001. When it is plus it receives?—Yes, it receives more than it discharges; at the commencement of the 11 years the discharge was about 500,000,000 gallons per day derived from springs, and at the end of the 11 years very nearly 1,000,000,000 gallons per day, showing that at the termination of the period of 11 years, the subterranean reservoirs held more water than they did at the commencement.

3002. (*Mr. Harrison.*) The rainfall in the year 1866 appears to have been the largest rainfall in the 11 years, being 36·42 inches?—Yes.

3003. I observe at the foot of the table a note which states that one inch of rain over the Thames basin gives 53,375,000,000 gallons of water?—Yes. I may put in probably with advantage this map which gives the acreage of the Thames basin (*handing in a map*). That is a copy of the map which is appended to our first report on the Thames. (*See Appendix V.*)

3004. (*Chairman.*) This is the result of a careful survey, is it not?—It is taken from Greenhough's geological map of England and Wales. I will now hand in Table No. 3.

The witness delivered in the following table:

No. 3.

TABLE showing approximately the RAINFALL on the THAMES BASIN; the DISCHARGE by the THAMES at KINGSTON; the EVAPORATION and the Addition or Subtraction from the SUBTERRANEAN RESERVOIRS in millions of gallons, Half-yearly and Yearly.—April 1855 to April 1866.

							* 159,351			

NOTE.—The rainfall is calculated from the averages of records kept by James Simpson, Esq., C.E., at Kingston, and T. Brown, Esq., at Cirencester.

The discharge is calculated from data supplied to the Rivers Commission by James Simpson, Esq., C.E.

The evaporation is calculated from observations on percolation by John Evans, Esq. of King's Langley, with an addition for extra evaporation from the clay in winter.

* The average daily discharge at Kingston between April 1858 and April 1859 was 803 million gallons per day.
" " " April 1864 " 1865 was 1,000 " "

J. T. Harrison, Esq.

9 May 1867.

3005. Will you explain table No. 3?—No. 3 is a similar table to No. 2, only instead of the rainfall discharge and evaporation being in inches they are given in millions of gallons.

3006. (*Mr. Harrison.*) For the purposes of this inquiry is not the most important point in this table the amount of the average yearly discharge over the 11 years at Kingston?—Yes.

3007. From this table it appears that the least amount was in the year 1858, when the quantity over the whole year amounted to 293,143,000,000 gallons?—Yes, that is the total quantity.

3008. The next smallest quantity appears to have been 364,974,000,000 gallons, was that the total quantity in the whole year?—Yes, in 1863 the volume discharged was 375,718,000,000 gallons. The rainfall during those three years was in 1858, 1,313,024,000,000 gallons; in 1864, 1,251,109,000,000 gallons; and in 1863, 1,437,922,000,000 gallons.

3009. Is that the total rainfall in the whole year?—Yes.

3010. Then there is the question of the actual discharge?—Yes, I have also a table which I think it would be well to mark No. 3A, which gives the number of days in each month during those three years when the water was lowest. It gives in the first column the number of days in each of those years when the volume of water discharged daily at Kingston was below 400,000,000 gallons per day; in the second column between 400,000,000 and 500,000,000 gallons per day, and in the third column between 500,000,000 and 600,000,000 gallons per day; in the fourth, between 600,000,000 and 700,000,000 per day, and so on. I take those three years, 1858, 1859, and 1864, as being the driest years during the 11 years, 1858 and 1859 being successive years which were the most important years as regards the water supply of the Thames. I will now hand in that table.

The witness delivered in the following table:

No. 3A.

TABLE showing the NUMBER of DAYS in the years 1858, 1859, and 1864, on which the VOLUME of WATER passing down the THAMES at KINGSTON was under 400,000,000 gallons per day:—

The number of days when the flow was between 400 and 500 million gallons per day
Ditto ditto 500 „ 600 ditto
Ditto ditto 600 „ 700 ditto
Ditto ditto 700 „ 800 ditto
Ditto ditto 800 „ 900 ditto
Ditto ditto 900 „ 1,000 ditto
Ditto ditto above 1,000 million gallons per day.

	Number of Days when the Volume was							
	Below 400 Million Gallons per Day.	Between 400 and 500 Million Gallons per Day.	Between 500 and 600 Million Gallons per Day.	Between 600 and 700 Million Gallons per Day.	Between 700 and 800 Million Gallons per Day.	Between 800 and 900 Million Gallons per Day.	Between 900 and 1,000 Million Gallons per Day.	Above 1,000 Million Gallons per Day.
1858.								
January	—	—	1	5	11	11	2	1
February	—	—	—	—	—	2	8	18
March	—	—	—	6	7	5	7	6
April	—	—	—	1	1	2	6	20
May	—	—	—	3	5	10	4	9
June	2	5	12	10	1	—	—	—
July	5	16	10	—	—	—	—	—

September	7	14	4	2	1	2	—	—
October	—	1	14	6	1	2	2	5
November	—	—	—	—	3	9	3	15
December	—	4	1	—	1	—	—	25
	32	54	38	39	38	51	26	87

There were 14 days in July, August, and September 1859 when the volume of water flowing past Kingston-on-Thames was about 350,000,000 gallons per day.

No. 3A.—TABLE showing the Number of Days in the Years 1858, 1859, and 1864, on which the Volume of Water passing down the Thames at Kingston was under 400,000,000 Gallons per Day—*continued.*

	Number of Days when the Volume was							
	Below 400 Million Gallons per Day.	Between 400 and 500 Million Gallons per Day.	Between 500 and 600 Million Gallons per Day.	Between 600 and 700 Million Gallons per Day.	Between 700 and 800 Million Gallons per Day.	Between 800 and 900 Million Gallons per Day.	Between 900 and 1,000 Million Gallons per Day.	Above 1,000 Million Gallons per Day.
1864.								
January	5	3	1	1	5	1	5	10
February	—	—	—	1	7	5	11	5
March	—	—	—	—	—	—	—	31
April	—	—	—	1	—	7	3	19
May	—	—	1	6	5	12	3	4
June	—	—	1	10	7	12	—	—
July	—	10	10	9	2	—	—	—
August	2	11	17	1	—	—	—	—
September	—	—	14	10	5	1	—	—
October	1	—	16	10	4	—	—	—
November	—	1	9	13	3	1	1	2
December	—	2	2	6	13	1	5	2
	8	27	71	68	51	40	28	73

There were two days in August 1864 when the volume of water flowing past Kingston-on-Thames was about 350,000,000 gallons per day.

3011. The result of that table is this, is it not, that in the year 1858, during the months of June, July, August, and September, there were 36 days in which the discharge at Kingston was below 400,000,000 gallons per day?—Yes, and you will see the note below, which is important; "there were 20 "days in June, July, August, and September when "the volume of water flowing past Kingston-on-"Thames was about 350,000,000 gallons per day."

3012. (*Col. Harness.*) Would not that be after the water companies had taken out the water?—No, it is above Kingston; the gaugings were taken at a point above the works of three of the water companies.

3013. (*Mr. Harrison.*) During the year 1859 there were again 32 days in which the supply was below 400,000,000 gallons daily?—Yes.

3014. And the note to that is, "there were 14 days "in July, August, and September 1859, when the "volume of water flowing past Kingston-on-Thames "was about 350,000,000 gallons per day"?—Yes.
